# GEOMETRY AND TRIGONOMETRY.

TRANSLATED FROM THE FRENCH OF

A. M. LEGENDRE,

BY DAVID BREWSTER, LL. D.

REVISED AND ADAPTED TO THE COURSE OF MATHEMATICAL INSTRUCTION  
IN THE UNITED STATES,

BY CHARLES DAVIES,

AUTHOR OF ARITHMETIC, ALGEBRA, PRACTICAL GEOMETRY, ELEMENTS OF  
DESCRIPTIVE AND OF ANALYTICAL GEOMETRY, ELEMENTS OF  
DIFFERENTIAL AND INTEGRAL CALCULUS, AND  
SHADES SHADOWS, AND PERSPECTIVE.

NEW YORK:

PUBLISHED BY A. S. BARNES & CO.

No. 51 JOHN STREET.

1847.

# DAVIES'

## COURSE OF MATHEMATICS.

---

**DAVIES' FIRST LESSONS IN ARITHMETIC**—For Beginners.

**DAVIES' ARITHMETIC**—Designed for the use of Academies and Schools.

**KEY TO DAVIES' ARITHMETIC.**

**DAVIES' UNIVERSITY ARITHMETIC**—Embracing the Science of Numbers and their numerous Applications.

**KEY TO DAVIES' UNIVERSITY ARITHMETIC.**

**DAVIES' ELEMENTARY ALGEBRA**—Being an introduction to the Science, and forming a connecting link between ARITHMETIC and ALGEBRA.

**KEY TO DAVIES' ELEMENTARY ALGEBRA.**

**DAVIES' ELEMENTARY GEOMETRY.**—This work embraces the elementary principles of Geometry. The reasoning is plain and concise, but at the same time strictly rigorous.

**DAVIES' ELEMENTS OF DRAWING AND MENSURATION**—Applied to the Mechanic Arts.

**DAVIES' BOURDON'S ALGEBRA**—Including STURM'S THEOREM—Being an abridgment of the Work of M. BOURDON, with the addition of practical examples.

**DAVIES' LEGENDRE'S GEOMETRY AND TRIGONOMETRY**—Being an abridgment of the work of M. Legendre, with the addition of a Treatise on MENSURATION OF PLANES AND SOLIDS, and a Table of LOGARITHMS and LOGARITHMIC SINES.

**DAVIES' SURVEYING**—With a description and plates of the THEODOLITE, COMPASS, PLANE-TABLE, and LEVEL; also, Maps of the TOPOGRAPHICAL SIGNS adopted by the Engineer Department—an explanation of the method of surveying the Public Lands, and an Elementary Treatise on NAVIGATION.

**DAVIES' ANALYTICAL GEOMETRY**—Embracing the EQUATIONS OF THE POINT AND STRAIGHT LINE—of the CONIC SECTIONS—of the LINE AND PLANE IN SPACE; also, the discussion of the GENERAL EQUATION of the second degree, and of SURFACES of the second order.

**DAVIES' DESCRIPTIVE GEOMETRY**—With its application to SPHERICAL PROJECTIONS.

**DAVIES' SHADOWS AND LINEAR PERSPECTIVE.**

**DAVIES' DIFFERENTIAL AND INTEGRAL CALCULUS.**

---

Entered, according to Act of Congress, in the year 1834, by CHARLES DAVIES, in the Clerk's Office of the District Court of the United States, in and for the Southern District of New York

# PREFACE

TO THE AMERICAN EDITION.

THE Editor, in offering to the public Dr. Brewster's translation of Legendre's Geometry under its present form, is fully impressed with the responsibility he assumes in making alterations in a work of such deserved celebrity.

In the original work, as well as in the translations of Dr. Brewster and Professor Farrar, the propositions are not enunciated in general terms, but with reference to, and by the aid of, the particular diagrams used for the demonstrations. It is believed that this departure from the method of Euclid has been generally regretted. The propositions of Geometry are general truths, and as such, should be stated in general terms, and without reference to particular figures. The method of enunciating them by the aid of particular diagrams seems to have been adopted to avoid the difficulty which beginners experience in comprehending abstract propositions. But in avoiding this difficulty, and thus lessening, at first, the intellectual labour, the faculty of abstraction, which it is one of the primary objects of the study of Geometry to strengthen, remains, to a certain extent, unimproved.

Besides the alterations in the enunciation of the propositions, others of considerable importance have also been made in the present edition. The proposition in Book V., which proves that a polygon and circle may be made to coincide so nearly, as to differ from each other by less than any assignable quantity, has been taken from the Edinburgh Encyclopedia. It is proved in the corollaries that a polygon of an infinite number of sides becomes a circle, and this principle is made the basis of several important demonstrations in Book VIII.

Book II., on Ratios and Proportions, has been partly adopted from the Encyclopedia Metropolitana, and will, it is believed, supply a deficiency in the original work.

Very considerable alterations have also been made in the manner of treating the subjects of Plane and Spherical Trigonometry. It has also been thought best to publish with the present edition a table of logarithms and logarithmic sines, and to apply the principles of geometry to the mensuration of surfaces and solids.

*Military Academy,*

*West Point, March, 1834.*

# CONTENTS.

## BOOK I.

|                           |   |
|---------------------------|---|
| The principles, . . . . . | 9 |
|---------------------------|---|

## BOOK II.

|                                   |    |
|-----------------------------------|----|
| Ratios and Proportions, . . . . . | 34 |
|-----------------------------------|----|

## BOOK III.

|   |    |
|---|----|
| The Circle and the Measurement of Angles, . . . . . | 41 |
|---|----|

|   |    |
|---|----|
| Problems relating to the First and Third Books, . . . . . | 57 |
|---|----|

## BOOK IV.

|  |    |
|--|----|
| The Proportions of Figures and the Measurement of Areas, . . . . . | 68 |
|--|----|

|   |    |
|---|----|
| Problems relating to the Fourth Book, . . . . . | 98 |
|---|----|

## BOOK V.

|   |     |
|---|-----|
| Regular Polygons and the Measurement of the Circle, . . . . . | 109 |
|---|-----|

## BOOK VI.

|                                    |     |
|------------------------------------|-----|
| Planes and Solid Angles, . . . . . | 126 |
|------------------------------------|-----|

## BOOK VII.

|                       |     |
|-----------------------|-----|
| Polyedrons, . . . . . | 142 |
|-----------------------|-----|

## BOOK VIII.

|                                   |    |
|-----------------------------------|----|
| The three round bodies, . . . . . | 16 |
|-----------------------------------|----|

## BOOK IX.

|  |     |
|--|-----|
| Of Spherical Triangles and Spherical Polygons, . . . . . | 186 |
|--|-----|

## APPENDIX.

|                                   |     |
|-----------------------------------|-----|
| The regular Polyedrons, . . . . . | 205 |
|-----------------------------------|-----|

## PLANE TRIGONOMETRY.

|  |     |
|--|-----|
| Division of the Circumference, . . . . .   | 207 |
| General Ideas relating to the Trigonometrical Lines, .                           | 208 |
| Theorems and Formulas relating to the Sines, Cosines, Tan-<br>gents, &c. . . . . | 215 |
| Construction and Description of the Tables, . . . .                              | 223 |
| Description of Table of Logarithms, . . . . .                                    | 224 |
| Description of Table of Logarithmic Sines, . . . .                               | 228 |
| Principles for the Solution of Rectilineal Triangles, . .                        | 231 |
| Solution of Rectilineal Triangles by Logarithms, . .                             | 235 |
| Solution of Right angled Triangles, . . . . .                                    | 237 |
| Solution of Triangles in general, . . . . .                                      | 238 |

## SPHERICAL TRIGONOMETRY.

|   |     |

# ELEMENTS OF GEOMETRY.

## BOOK I.

### THE PRINCIPLES.

#### *Definitions.*

1. GEOMETRY is the science which has for its object the measurement of extension.

Extension has three dimensions, length, breadth, and height, or thickness.

2. A *line* is length without breadth, or thickness.

The extremities of a line are called *points*: a point, therefore, has neither length, breadth, nor thickness, but position only.

3. A *straight line* is the shortest distance from one point to another.

4. Every line which is not straight, or composed of straight lines, is a *curved line*.

Thus, AB is a straight line; ACDB is a *broken* line, or one composed of straight lines; and AEB is a curved line.

The word *line*, when used alone, will designate a straight line; and the word *curve*, a curved line.

5. A *surface* is that which has length and breadth, without height or thickness.

6. A *plane* is a surface, in which, if two points be assumed at pleasure, and connected by a straight line, that line will lie wholly in the surface.

7. Every surface, which is not a plane surface, or composed of plane surfaces, is a *curved surface*.

8. A *solid* or *body* is that which has length, breadth, and thickness; and therefore combines the three dimensions of extension.

9. When two straight lines, AB, AC, meet each other, their inclination or opening is called an *angle*, which is greater or less as the lines are more or less inclined or opened. The point of intersection A is the vertex of the angle, and the lines AB, AC, are its sides.

The angle is sometimes designated simply by the letter at the vertex A; sometimes by the three letters BAC, or CAB, the letter at the vertex being always placed in the middle.

Angles, like all other quantities, are susceptible of addition, subtraction, multiplication, and division.

Thus the angle DCE is the sum of the two angles DCB, BCE; and the angle DCB is the difference of the two angles DCE, BCE.

10. When a straight line AB meets another straight line CD, so as to make the adjacent angles BAC, BAD, equal to each other, each of these angles is called a *right angle*; and the line AB is said to be *perpendicular* to CD.

11. Every angle BAC, less than a right angle, is an *acute angle*; and every angle DEF, greater than a right angle, is an *obtuse angle*.

12. Two lines are said to be *parallel*, when being situated in the same plane, they cannot meet, how far soever, either way, both of them be produced.

13. A *plane figure* is a plane terminated on all sides by lines, either straight or curved.

If the lines are straight, the space they enclose is called a *rectilineal figure*, or *polygon*, and the lines themselves, taken together, form the contour, or *perimeter* of the polygon.

14. The polygon of three sides, the simplest of all, is called a *triangle*; that of four sides, a *quadrilateral*; that of five, a *pentagon*; that of six, a *hexagon*; that of seven, a *heptagon*; that of eight, an *octagon*; that of nine, a *nonagon*; that of ten, a *decagon*; and that of twelve, a *dodecagon*.

15. An *equilateral* triangle is one which has its three sides equal; an *isosceles* triangle, one which has two of its sides equal; a *scalene* triangle, one which has its three sides unequal.

16. A right-angled triangle is one which has a right angle. The side opposite the right angle is called the *hypotenuse*. Thus, in the triangle ABC, right-angled at A, the side BC is the hypotenuse.

17. Among the quadrilaterals, we distinguish :

The *square*, which has its sides equal, and its angles right-angles.

The *rectangle*, which has its angles right angles, without having its sides equal.

The *parallelogram*, or *rhomboid*, which has its opposite sides parallel.

The *rhombus*, or *lozenge*, which has its sides equal, without having its angles right angles.

And lastly, the *trapezoid*, only two of whose sides are parallel.

18. A *diagonal* is a line which joins the vertices of two angles not adjacent to each other. Thus, AF, AE, AD, AC, are diagonals.

19. An *equilateral* polygon is one which has all its sides equal; an *equiangular* polygon, one which has all its angles equal.

20. Two polygons are *mutually equilateral*, when they have their sides equal each to each, and placed in the same order

that is to say, when following their perimeters in the same direction, the first side of the one is equal to the first side of the other, the second of the one to the second of the other, the third to the third, and so on. The phrase, *mutually equiangular*, has a corresponding signification, with respect to the angles.

In both cases, the equal sides, or the equal angles, are named *homologous* sides or angles.

### *Definitions of terms employed in Geometry.*

An *axiom* is a self-evident proposition.

A *theorem* is a truth, which becomes evident by means of a train of reasoning called a *demonstration*.

A *problem* is a question proposed, which requires a *solution*.

A *lemma* is a subsidiary truth, employed for the demonstration of a theorem, or the solution of a problem.

The common name, *proposition*, is applied indifferently, to theorems, problems, and lemmas.

A *corollary* is an obvious consequence, deduced from one or several propositions.

A *scholium* is a remark on one or several preceding propositions, which tends to point out their connexion, their use, their restriction, or their extension.

A *hypothesis* is a supposition, made either in the enunciation of a proposition, or in the course of a demonstration.

### *Explanation of the symbols to be employed.*

The sign  $=$  is the sign of equality; thus, the expression  $A=B$ , signifies that A is equal to B.

To signify that A is smaller than B, the expression  $A < B$  is used.

To signify that A is greater than B, the expression  $A > B$  is used; the smaller quantity being always at the vertex of the angle.

The sign  $+$  is called *plus*: it indicates addition.

The sign  $-$  is called *minus*: it indicates subtraction.

Thus,  $A+B$ , represents the sum of the quantities A and B;  $A-B$  represents their difference, or what remains after B is taken from A; and  $A-B+C$ , or  $A+C-B$ , signifies that A and C are to be added together, and that B is to be subtracted from their sum.

The sign  $\times$  indicates multiplication : thus,  $A \times B$  represents the product of  $A$  and  $B$ . Instead of the sign  $\times$ , a point is sometimes employed ; thus,  $A.B$  is the same thing as  $A \times B$ . The same product is also designated without any intermediate sign, by  $AB$  ; but this expression should not be employed, when there is any danger of confounding it with that of the line  $AB$ , which expresses the distance between the points  $A$  and  $B$ .

The expression  $A \times (B + C - D)$  represents the product of  $A$  by the quantity  $B + C - D$ . If  $A + B$  were to be multiplied by  $A - B + C$ , the product would be indicated thus,  $(A + B) \times (A - B + C)$ , whatever is enclosed within the curved lines, being considered as a single quantity.

A number placed before a line, or a quantity, serves as a multiplier to that line or quantity ; thus,  $3AB$  signifies that the line  $AB$  is taken three times ;  $\frac{1}{2}A$  signifies the half of the angle  $A$ .

The square of the line  $AB$  is designated by  $AB^2$  ; its cube by  $AB^3$ . What is meant by the square and cube of a line, will be explained in its proper place.

The sign  $\sqrt{\phantom{x}}$  indicates a root to be extracted ; thus  $\sqrt{2}$  means the square-root of 2 ;  $\sqrt{A \times B}$  means the square-root of the product of  $A$  and  $B$ .

### *Axioms.*

1. Things which are equal to the same thing, are equal to each other.

2. If equals be added to equals, the wholes will be equal.

3. If equals be taken from equals, the remainders will be equal.

4. If equals be added to unequals, the wholes will be unequal.

5. If equals be taken from unequals, the remainders will be unequal.

6. Things which are double of the same thing, are equal to each other.

7. Things which are halves of the same thing, are equal to each other.

8. The whole is greater than any of its parts.

9. The whole is equal to the sum of all its parts.

10. All right angles are equal to each other.

11. From one point to another only one straight line can be drawn.

12. Through the same point, only one straight line can be drawn which shall be parallel to a given line.

13. Magnitudes, which being applied to each other, coincide throughout their whole extent, are equal.

## PROPOSITION I. THEOREM.

*If one straight line meet another straight line, the sum of the two adjacent angles will be equal to two right angles.*

Let the straight line DC meet the straight line AB at C, then will the angle ACD + the angle DCB, be equal to two right angles.

At the point C, erect CE perpendicular to AB. The angle ACD is the sum of the angles ACE, ECD: therefore  $ACD + DCB$  is the sum of the three angles ACE, ECD, DCB: but the first of these three angles is a right angle, and the other two make up the right angle ECB; hence, the sum of the two angles ACD and DCB, is equal to two right angles.

*Cor. 1.* If one of the angles ACD, DCB, is a right angle, the other must be a right angle also.

*Cor. 2.* If the line DE is perpendicular to AB, reciprocally, AB will be perpendicular to DE.

For, since DE is perpendicular to AB, the angle ACD must be equal to its adjacent angle DCB, and both of them must be right angles (Def. 10.). But since ACD is a right angle, its adjacent angle ACE must also be a right angle (Cor. 1.). Hence the angle ACD is equal to the angle ACE, (Ax. 10.): therefore AB is perpendicular to DE.

*Cor. 3.* The sum of all the successive angles, BAC, CAD, DAE, EAF, formed on the same side of the straight line BF, is equal to two right angles; for their sum is equal to that of the two adjacent angles, BAC, CAF.

## PROPOSITION II. THEOREM.

*Two straight lines, which have two points common, coincide with each other throughout their whole extent, and form one and the same straight line.*

Let A and B be the two common points. In the first place it is evident that the two lines must coincide entirely between A and B, for otherwise there would be two straight lines between A and B, which is impossible (Ax. 11). Sup-

pose, however, that on being produced, these lines begin to separate at C, the one becoming CD, the other CE. From the point C draw the line CF, making with AC the right angle ACF. Now, since ACD is a straight line, the angle FCD will be a right angle (Prop. I. Cor. 1.); and since ACE is a straight line, the angle FCE will likewise be a right angle. Hence, the angle FCD is equal to the angle FCE (Ax. 10.); which can only be the case when the lines CD and CE coincide: therefore, the straight lines which have two points A and B common, cannot separate at any point, when produced; hence they form one and the same straight line.

### PROPOSITION III. THEOREM.

*If a straight line meet two other straight lines at a common point, making the sum of the two adjacent angles equal to two right angles, the two straight lines which are met, will form one and the same straight line.*

Let the straight line CD meet the two lines AC, CB, at their common point C, making the sum of the two adjacent angles DCA, DCB, equal to two right angles; then will CB be the prolongation of AC, or AC and CB will form one and the same straight line.

For, if CB is not the prolongation of AC, let CE be that prolongation: then the line ACE being straight, the sum of the angles ACD, DCE, will be equal to two right angles (Prop. I.). But by hypothesis, the sum of the angles ACD, DCB, is also equal to two right angles: therefore,  $ACD + DCE$  must be equal to  $ACD + DCB$ ; and taking away the angle ACD from each, there remains the angle DCE equal to the angle DCB, which can only be the case when the lines CE and CB coincide; hence, AC, CB, form one and the same straight line.

### PROPOSITION IV. THEOREM.

*When two straight lines intersect each other, the opposite or vertical angles, which they form, are equal.*

Let  $AB$  and  $DE$  be two straight lines, intersecting each other at  $C$ ; then will the angle  $ECB$  be equal to the angle  $ACD$ , and the angle  $ACE$  to the angle  $DCB$ .

For, since the straight line  $DE$  is met by the straight line  $AC$ , the sum of the angles  $ACE$ ,  $ACD$ , is equal to two right angles (Prop. I.); and since the straight line  $AB$ , is met by the straight line  $EC$ , the sum of the angles  $ACE$  and  $ECB$ , is equal to two right angles: hence the sum  $ACE + ACD$  is equal to the sum  $ACE + ECB$  (Ax. 1.). Take away from both, the common angle  $ACE$ , there remains the angle  $ACD$ , equal to its opposite or vertical angle  $ECB$  (Ax. 3.).

*Scholium.* The four angles formed about a point by two straight lines, which intersect each other, are together equal to four right angles: for the sum of the two angles  $ACE$ ,  $ECB$ , is equal to two right angles; and the sum of the other two,  $ACD$ ,  $DCB$ , is also equal to two right angles: therefore, the sum of the four is equal to four right angles.

In general, if any number of straight lines  $CA$ ,  $CB$ ,  $CD$ , &c. meet in a point  $C$ , the sum of all the successive angles  $ACB$ ,  $BCD$ ,  $DCE$ ,  $ECF$ ,  $FCA$ , will be equal to four right angles: for, if four right angles were formed about the point  $C$ , by two lines perpendicular to each other, the same space would be occupied by the four right angles, as by the successive angles  $ACB$ ,  $BCD$ ,  $DCE$ ,  $ECF$ ,  $FCA$ .

#### PROPOSITION V. THEOREM.

*If two triangles have two sides and the included angle of the one, equal to two sides and the included angle of the other, each to each, the two triangles will be equal*

Let the side  $ED$  be equal to the side  $BA$ , the side  $DF$  to the side  $AC$ , and the angle  $D$  to the angle  $A$ ; then will the triangle  $EDF$  be equal to the triangle  $BAC$ .

For, these triangles may be so applied to each other, that they shall exactly coincide. Let the triangle  $EDF$ , be placed upon the triangle  $BAC$ , so that the point  $E$  shall fall upon  $B$ , and the side  $ED$  on the equal side  $BA$ ; then, since the angle  $D$  is equal to the angle  $A$ , the side  $DF$  will take the direction  $AC$ . But

DF is equal to AC ; therefore, the point F will fall on C, and the third side EF, will coincide with the third side BC (Ax. 11.): therefore, the triangle EDF is equal to the triangle BAC (Ax. 13.).

*Cor.* When two triangles have these three things equal, namely, the side  $ED=BA$ , the side  $DF=AC$ , and the angle  $D=A$ , the remaining three are also respectively equal, namely, the side  $EF=BC$ , the angle  $E=B$ , and the angle  $F=C$

#### PROPOSITION VI. THEOREM.

*If two triangles have two angles and the included side of the one, equal to two angles and the included side of the other, each to each, the two triangles will be equal.*

Let the angle E be equal to the angle B, the angle F to the angle C, and the included side EF to the included side BC ; then will the triangle EDF be equal to the triangle BAC.

For to apply the one to the other, let the side EF be placed on its equal BC, the point E falling on B, and the point F on C ; then, since the angle E is equal to the angle B, the side ED will take the direction BA ; and hence the point D will be found somewhere in the line BA. In like manner, since the angle F is equal to the angle C, the line FD will take the direction CA, and the point D will be found somewhere in the line CA. Hence, the point D, falling at the same time in the two straight lines BA and CA, must fall at their intersection A : hence, the two triangles EDF, BAC, coincide with each other, and are therefore equal (Ax. 13.).

*Cor.* Whenever, in two triangles, these three things are equal, namely, the angle  $E=B$ , the angle  $F=C$ , and the included side EF equal to the included side BC, it may be inferred that the remaining three are also respectively equal, namely, the angle  $D=A$ , the side  $ED=BA$ , and the side  $DF=AC$ .

*Scholium.* Two triangles are said to be equal, when being applied to each other, they will exactly coincide (Ax. 13.). Hence, equal triangles have their like parts equal, each to each, since those parts must coincide with each other. The converse of this proposition is also true, namely, that *two triangles which have all the parts of the one equal to the parts of the other, each*

to each, are equal; for they may be applied to each other, and the equal parts will mutually coincide.

PROPOSITION VII. THEOREM.

*The sum of any two sides of a triangle, is greater than the third side.*

Let  $ABC$  be a triangle: then will the sum of two of its sides, as  $AC$ ,  $CB$ , be greater than the third side  $AB$ .

For the straight line  $AB$  is the shortest distance between the points  $A$  and  $B$  (Def. 3.); hence  $AC + CB$  is greater than  $AB$ .

PROPOSITION VIII. THEOREM.

*If from any point within a triangle, two straight lines be drawn to the extremities of either side, their sum will be less than the sum of the two other sides of the triangle.*

Let any point, as  $O$ , be taken within the triangle  $BAC$ , and let the lines  $OB$ ,  $OC$ , be drawn to the extremities of either side, as  $BC$ ; then will  $OB + OC < BA + AC$ .

Let  $BO$  be produced till it meets the side  $AC$  in  $D$ : then the line  $OC$  is shorter than  $OD + DC$  (Prop. VII.): add  $BO$  to each, and we have  $BO + OC < BO + OD + DC$  (Ax. 4.), or  $BO + OC < BD + DC$ .

Again,  $BD < BA + AD$ : add  $DC$  to each, and we have  $BD + DC < BA + AC$ . But it has just been found that  $BO + OC < BD + DC$ ; therefore, still more is  $BO + OC < BA + AC$ .

PROPOSITION IX. THEOREM.

*If two triangles have two sides of the one equal to two sides of the other, each to each, and the included angles unequal, the third sides will be unequal; and the greater side will belong to the triangle which has the greater included angle.*

Let  $BAC$  and  $EDF$  be two triangles, having the side  $AB = DE$ ,  $AC = DF$ , and the angle  $A > D$ ; then will  $BC > EF$ .

Make the angle  $CAG = D$ ; take  $AG = DE$ , and draw  $CG$ . The

triangle  $GAC$  is equal to  $DEF$ , since, by construction, they have an equal angle in each, contained by equal sides, (Prop. V.); therefore  $CG$  is equal to  $EF$ . Now, there may be three cases in the proposition, according as the point  $G$  falls without the triangle  $ABC$ , or upon its base  $BC$ , or within it.

*First Case.* The straight line  $GC < GI + IC$ , and the straight line  $AB < AI + IB$ ; therefore,  $GC + AB < GI + AI + IC + IB$ , or, which is the same thing,  $GC + AB < AG + BC$ . Take away  $AB$  from the one side, and its equal  $AG$  from the other; and there remains  $GC < BC$  (Ax. 5.); but we have found  $GC = EF$ , therefore,  $BC > EF$ .

*Second Case.* If the point  $G$  fall on the side  $BC$ , it is evident that  $GC$ , or its equal  $EF$ , will be shorter than  $BC$  (Ax. 8.).

*Third Case.* Lastly, if the point  $G$  fall within the triangle  $BAC$ , we shall have, by the preceding theorem,  $AG + GC < AB + BC$ ; and, taking  $AG$  from the one, and its equal  $AB$  from the other, there will remain  $GC < BC$  or  $BC > EF$ .

*Scholium.* Conversely, if two sides  $BA$ ,  $AC$ , of the triangle  $BAC$ , are equal to the two  $ED$ ,  $DF$ , of the triangle  $EDF$ , each to each, while the third side  $BC$  of the first triangle is greater than the third side  $EF$  of the second; then will the angle  $BAC$  of the first triangle, be greater than the angle  $EDF$  of the second.

For, if not, the angle  $BAC$  must be equal to  $EDF$ , or less than it. In the first case, the side  $BC$  would be equal to  $EF$ , (Prop. V. Cor.); in the second,  $CB$  would be less than  $EF$ ; but either of these results contradicts the hypothesis: therefore,  $BAC$  is greater than  $EDF$ .

#### PROPOSITION X. THEOREM.

*If two triangles have the three sides of the one equal to the three sides of the other, each to each, the three angles will also be equal, each to each, and the triangles themselves will be equal.*

Let the side  $ED=BA$ , the side  $EF=BC$ , and the side  $DF=AC$ ; then will the angle  $D=A$ , the angle  $E=B$ , and the angle  $F=C$ .

For, if the angle  $D$  were greater than  $A$ , while the sides  $ED, DF$ , were equal to  $BA, AC$ , each to each, it would follow, by the last proposition, that the side  $EF$  must be greater than  $BC$ ; and if the angle  $D$  were less than  $A$ , it would follow, that the side  $EF$  must be less than  $BC$ : but  $EF$  is equal to  $BC$ , by hypothesis; therefore, the angle  $D$  can neither be greater nor less than  $A$ ; therefore it must be equal to it. In the same manner it may be shown that the angle  $E$  is equal to  $B$ , and the angle  $F$  to  $C$ : hence the two triangles are equal (Prop. VI. Sch.).

*Scholium.* It may be observed that the equal angles lie opposite the equal sides: thus, the equal angles  $D$  and  $A$ , lie opposite the equal sides  $EF$  and  $BC$ .

#### PROPOSITION XI. THEOREM.

*In an isosceles triangle, the angles opposite the equal sides are equal.*

Let the side  $BA$  be equal to the side  $AC$ ; then will the angle  $C$  be equal to the angle  $B$ .

For, join the vertex  $A$ , and  $D$  the middle point of the base  $BC$ . Then, the triangles  $BAD, DAC$ , will have all the sides of the one equal to those of the other, each to each; for  $BA$  is equal to  $AC$ , by hypothesis;  $AD$  is common, and  $BD$  is equal to  $DC$  by construction: therefore, by the last proposition, the angle  $B$  is equal to the angle  $C$ .

*Cor.* An equilateral triangle is likewise equiangular, that is to say, has all its angles equal.

*Scholium.* The equality of the triangles  $BAD, DAC$ , proves also that the angle  $BAD$ , is equal to  $DAC$ , and  $BDA$  to  $ADC$ , hence the latter two are right angles; therefore, the line drawn from the vertex of an isosceles triangle to the middle point of its base, is perpendicular to the base, and divides the angle at the vertex into two equal parts.

In a triangle which is not isosceles, any side may be assumed indifferently as the *base*; and the *vertex* is, in that case, the vertex of the opposite angle. In an isosceles triangle, however,

that side is generally assumed as the base, which is not equal to either of the other two.

## PROPOSITION XII. THEOREM.

*Conversely, if two angles of a triangle are equal, the sides opposite them are also equal, and the triangle is isosceles.*

Let the angle  $ABC$  be equal to the angle  $ACB$ ; then will the side  $AC$  be equal to the side  $AB$ .

For, if these sides are not equal, suppose  $AB$  to be the greater. Then, take  $BD$  equal to  $AC$ , and draw  $CD$ . Now, in the two triangles  $BDC$ ,  $BAC$ , we have  $BD=AC$ , by construction; the angle  $B$  equal to the angle  $ACB$ , by hypothesis; and the side  $BC$  common: therefore, the two triangles,  $BDC$ ,  $BAC$ , have two sides and the included angle in the one, equal to two sides and the included angle in the other, each to each: hence they are equal (Prop. V.). But the part cannot be equal to the whole (Ax. 8.); hence, there is no inequality between the sides  $BA$ ,  $AC$ ; therefore, the triangle  $BAC$  is isosceles.

## PROPOSITION XIII. THEOREM.

*The greater side of every triangle is opposite to the greater angle; and conversely, the greater angle is opposite to the greater side.*

First, Let the angle  $C$  be greater than the angle  $B$ ; then will the side  $AB$ , opposite  $C$ , be greater than  $AC$ , opposite  $B$ .

For, make the angle  $BCD=B$ . Then, in the triangle  $CDB$ , we shall have  $CD=BD$  (Prop. XII.). Now, the side  $AC < AD + CD$ ; but  $AD + CD = AD + DB = AB$ : therefore  $AC < AB$ .

Secondly, Suppose the side  $AB > AC$ ; then will the angle  $C$ , opposite to  $AB$ , be greater than the angle  $B$ , opposite to  $AC$ .

For, if the angle  $C < B$ , it follows, from what has just been proved, that  $AB < AC$ ; which is contrary to the hypothesis. If the angle  $C = B$ , then the side  $AB = AC$  (Prop. XII.); which is also contrary to the supposition. Therefore, when  $AB > AC$ , the angle  $C$  must be greater than  $B$ .

## PROPOSITION XIV. THEOREM.

*From a given point, without a straight line, only one perpendicular can be drawn to that line.*

Let A be the point, and DE the given line.

Let us suppose that we can draw two perpendiculars, AB, AC. Produce either of them, as AB, till BF is equal to AB, and draw FC. Then, the two triangles CAB, CBF, will be equal: for, the angles CBA, and CBF are right angles, the side CB is common, and the side AB equal to BF, by construction; therefore, the triangles are equal, and the angle ACB = BCF (Prop. V. Cor.). But the angle ACB is a right angle, by hypothesis; therefore, BCF must likewise be a right angle. But if the adjacent angles BCA, BCF, are together equal to two right angles, ACF must be a straight line (Prop. III.): from whence it follows, that between the same two points, A and F, two straight lines can be drawn, which is impossible (Ax. 11.): hence, two perpendiculars cannot be drawn from the same point to the same straight line.

*Scholium.* At a given point C, in the line AB, it is equally impossible to erect two perpendiculars to that line. For, if CD, CE, were those two perpendiculars, the angles BCD, BCE, would both be right angles: hence they would be equal (Ax. 10.); and the line CD would coincide with CE; otherwise, a part would be equal to the whole, which is impossible (Ax. 8.).

## PROPOSITION XV. THEOREM.

*If from a point without a straight line, a perpendicular be let fall on the line, and oblique lines be drawn to different points:*

*1st, The perpendicular will be shorter than any oblique line.*

*2d, Any two oblique lines, drawn on different sides of the perpendicular, cutting off equal distances on the other line, will be equal.*

*3d, Of two oblique lines, drawn at pleasure, that which is farther from the perpendicular will be the longer.*

Let  $A$  be the given point,  $DE$  the given line,  $AB$  the perpendicular, and  $AD$ ,  $AC$ ,  $AE$ , the oblique lines.

Produce the perpendicular  $AB$  till  $BF$  is equal to  $AB$ , and draw  $FC$ ,  $FD$ .

*First.* The triangle  $BCF$ , is equal to the triangle  $BCA$ , for they have the right angle  $CBF = CBA$ , the side  $CB$  common, and the side  $BF = BA$ ; hence the third sides,  $CF$  and  $CA$  are equal (Prop. V. Cor.). But  $ABF$ , being a straight line, is shorter than  $ACF$ , which is a broken line (Def. 3.); therefore,  $AB$ , the half of  $ABF$ , is shorter than  $AC$ , the half of  $ACF$ ; hence, the perpendicular is shorter than any oblique line.

*Secondly.* Let us suppose  $BC = BE$ ; then will the triangle  $CAB$  be equal to the triangle  $BAE$ ; for  $BC = BE$ , the side  $AB$  is common, and the angle  $CBA = ABE$ ; hence the sides  $AC$  and  $AE$  are equal (Prop. V. Cor.): therefore, two oblique lines, equally distant from the perpendicular, are equal.

*Thirdly.* In the triangle  $DFA$ , the sum of the lines  $AC$ ,  $CF$ , is less than the sum of the sides  $AD$ ,  $DF$  (Prop. VIII.); therefore,  $AC$ , the half of the line  $ACF$ , is shorter than  $AD$ , the half of the line  $ADF$ : therefore, the oblique line, which is farther from the perpendicular, is longer than the one which is nearer.

*Cor. 1.* The perpendicular measures the shortest distance of a point from a line.

*Cor. 2.* From the same point to the same straight line, only two equal straight lines can be drawn; for, if there could be more, we should have at least two equal oblique lines on the same side of the perpendicular, which is impossible.

#### PROPOSITION XVI. THEOREM.

*If from the middle point of a straight line, a perpendicular be drawn to this line;*

*1st, Every point of the perpendicular will be equally distant from the extremities of the line.*

*2d, Every point, without the perpendicular, will be unequally distant from those extremities.*

Let  $AB$  be the given straight line,  $C$  the middle point, and  $ECF$  the perpendicular.

*First*, Since  $AC=CB$ , the two oblique lines  $AD, DB$ , are equally distant from the perpendicular, and therefore equal (Prop. XV.). So, likewise, are the two oblique lines  $AE, EB$ , the two  $AF, FB$ , and so on. Therefore every point in the perpendicular is equally distant from the extremities  $A$  and  $B$ .

*Secondly*, Let  $I$  be a point out of the perpendicular. If  $IA$  and  $IB$  be drawn, one of these lines will cut the perpendicular in  $D$ ; from which, drawing  $DB$ , we shall have  $DB=DA$ . But the straight line  $IB$  is less than  $ID+DB$ , and  $ID+DB=ID+DA=IA$ ; therefore,  $IB < IA$ ; therefore, every point out of the perpendicular, is unequally distant from the extremities  $A$  and  $B$ .

*Cor.* If a straight line have two points  $D$  and  $F$ , equally distant from the extremities  $A$  and  $B$ , it will be perpendicular to  $AB$  at the middle point  $C$ .

#### PROPOSITION XVII. THEOREM.

*If two right angled triangles have the hypotenuse and a side of the one, equal to the hypotenuse and a side of the other, each to each, the remaining parts will also be equal, each to each, and the triangles themselves will be equal.*

In the two right angled triangles  $BAC, EDF$ , let the hypotenuse  $AC=DF$ , and the side  $BA=ED$ : then will the side  $BC=EF$ , the angle  $A=D$ , and the angle  $C=F$ .

If the side  $BC$  is equal to  $EF$ , the like angles of the two triangles are equal (Prop. X.). Now, if it be possible, suppose these two sides to be unequal, and that  $BC$  is the greater.

On  $BC$  take  $BG=EF$ , and draw  $AG$ . Then, in the two triangles  $BAG, DEF$ , the angles  $B$  and  $E$  are equal, being right angles, the side  $BA=ED$  by hypothesis, and the side  $BG=EF$  by construction: consequently,  $AG=DF$  (Prop. V. Cor.). But by hypothesis  $AC=DF$ ; and therefore,  $AC=AG$  (Ax. 1.). But the oblique line  $AC$  cannot be equal to  $AG$ , which lies nearer the perpendicular  $AB$  (Prop. XV.); therefore,  $BC$  and  $EF$  cannot be unequal, and hence the angle  $A=D$ , and the angle  $C=F$ ; and therefore, the triangles are equal (Prop. VI. Sch.).

## PROPOSITION XVIII. THEOREM.

*If two straight lines are perpendicular to a third line, they will be parallel to each other : in other words, they will never meet, how far soever either way, both of them be produced.*

Let the two lines AC, BD, be perpendicular to AB; then will they be parallel.

For, if they could meet in a point O, on either side of AB, there would be two perpendiculars OA, OB, let fall from the same point on the same straight line; which is impossible (Prop. XIV.).

## PROPOSITION XIX. THEOREM.

*If two straight lines meet a third line, making the sum of the interior angles on the same side of the line met, equal to two right angles, the two lines will be parallel.*

Let the two lines EC, BD, meet the third line BA, making the angles BAC, ABD, together equal to two right angles: then the lines EC, BD, will be parallel.

From G, the middle point of BA, draw the straight line EGF, perpendicular to EC. It will also be perpendicular to BD. For, the sum  $BAC + ABD$  is equal to two right angles, by hypothesis; the sum  $BAC + BAE$  is likewise equal to two right angles (Prop. I.); and taking away BAC from both, there will remain the angle  $ABD = BAE$ .

Again, the angles EGA, BGF, are equal (Prop. IV.); therefore, the triangles EGA and BGF, have each a side and two adjacent angles equal; therefore, they are themselves equal, and the angle GEA is equal to the angle GFB (Prop. VI. Cor.): but GEA is a right angle by construction; therefore, GFB is a right angle; hence the two lines EC, BD, are perpendicular to the same straight line, and are therefore parallel (Prop. XVIII.).

*Scholium.* When two parallel straight lines  $AB$ ,  $CD$ , are met by a third line  $FE$ , the angles which are formed take particular names.

*Interior angles on the same side*, are those which lie within the parallels, and on the same side of the secant line: thus,  $OGB$ ,  $GOD$ , are interior angles on the same side; and so also are the angles  $OGA$ ,  $GOC$ .

*Alternate angles* lie within the parallels, and on different sides of the secant line:  $AGO$ ,  $DGO$ , are alternate angles; and so also are the angles  $COG$ ,  $BGO$ .

*Alternate exterior angles* lie without the parallels, and on different sides of the secant line:  $EGB$ ,  $COF$ , are alternate exterior angles; so also, are the angles  $AGE$ ,  $FOD$ .

*Opposite exterior and interior angles* lie on the same side of the secant line, the one without and the other within the parallels, but not adjacent: thus,  $EGB$ ,  $GOD$ , are opposite exterior and interior angles; and so also, are the angles  $AGE$ ,  $GOC$ .

*Cor. 1.* If a straight line  $EF$ , meet two straight lines  $CD$ ,  $AB$ , making the alternate angles  $AGO$ ,  $GOD$ , equal to each other, the two lines will be parallel. For, to each add the angle  $OGB$ ; we shall then have,  $AGO + OGB = GOD + OGB$ ; but  $AGO + OGB$  is equal to two right angles (Prop. I.); hence  $GOD + OGB$  is equal to two right angles: therefore,  $CD$ ,  $AB$ , are parallel.

*Cor. 2.* If a straight line  $EF$ , meet two straight lines  $CD$ ,  $AB$ , making the exterior angle  $EGB$  equal to the interior and opposite angle  $GOD$ , the two lines will be parallel. For, to each add the angle  $OGB$ : we shall then have  $EGB + OGB = GOD + OGB$ ; but  $EGB + OGB$  is equal to two right angles; hence,  $GOD + OGB$  is equal to two right angles; therefore,  $CD$ ,  $AB$ , are parallel.

#### PROPOSITION XX. THEOREM.

*If a straight line meet two parallel straight lines, the sum of the interior angles on the same side will be equal to two right angles.*

Let the parallels  $AB$ ,  $CD$ , be met by the secant line  $FE$ : then will  $OGB + GOD$ , or  $OGA + GOC$ , be equal to two right angles.

For, if  $OGB + GOD$  be not equal to two right angles, let  $IGH$  be drawn, making the sum  $OGH + GOD$  equal to two

right angles; then  $IH$  and  $CD$  will be parallel (Prop. XIX.), and hence we shall have two lines  $GB$ ,  $GH$ , drawn through the same point  $G$  and parallel to  $CD$ , which is impossible (Ax. 12.): hence,  $GB$  and  $GH$  should coincide, and  $\angle OGB + \angle GOD$  is equal to two right angles. In the same manner it may be proved that  $\angle OGA + \angle GOC$  is equal to two right angles.

*Cor. 1.* If  $\angle OGB$  is a right angle,  $\angle GOD$  will be a right angle also: therefore, *every straight line perpendicular to one of two parallels, is perpendicular to the other.*

*Cor. 2.* If a straight line meet two parallel lines, the alternate angles will be equal.

Let  $AB$ ,  $CD$ , be the parallels, and  $FE$  the secant line. The sum  $\angle OGB + \angle GOD$  is equal to two right angles. But the sum  $\angle OGB + \angle OGA$  is also equal to two right angles (Prop. I.). Taking from each, the angle  $\angle OGB$ , and there remains  $\angle OGA = \angle GOD$ . In the same manner we may prove that  $\angle GOC = \angle OGB$ .

*Cor. 3.* If a straight line meet two parallel lines, the opposite exterior and interior angles will be equal. For, the sum  $\angle OGB + \angle GOD$  is equal to two right angles. But the sum  $\angle OGB + \angle EGB$  is also equal to two right angles. Taking from each the angle  $\angle OGB$ , and there remains  $\angle GOD = \angle EGB$ . In the same manner we may prove that  $\angle AGE = \angle GOC$ .

*Cor. 4.* We see that of the eight angles formed by a line cutting two parallel lines obliquely, the four acute angles are equal to each other, and so also are the four obtuse angles.

#### PROPOSITION XXI. THEOREM.

*If a straight line meet two other straight lines, making the sum of the interior angles on the same side less than two right angles, the two lines will meet if sufficiently produced.*

Let the line  $EF$  meet the two lines  $CD$ ,  $IH$ , making the sum of the interior angles  $\angle OGH$ ,  $\angle GOD$ , less than two right angles: then will  $IH$  and  $CD$  meet if sufficiently produced.

For, if they do not meet they are parallel (Def. 12.). But they are not parallel, for if they were, the sum of the interior angles  $\angle OGH$ ,  $\angle GOD$ , would be equal to two right angles (Prop. XX.), whereas it is less by hypothesis: hence, the lines  $IH$ ,  $CD$ , are not parallel, and will therefore meet if sufficiently produced.

*Cor.* It is evident that the two lines  $IH$ ,  $CD$ , will meet on that side of  $EF$  on which the sum of the two angles  $OGH$ ,  $GOD$ , is less than two right angles

PROPOSITION XXII. THEOREM.

*Two straight lines which are parallel to a third line, are parallel to each other.*

Let  $CD$  and  $AB$  be parallel to the third line  $EF$ ; then are they parallel to each other.

Draw  $PQR$  perpendicular to  $EF$ , and cutting  $AB$ ,  $CD$ . Since  $AB$  is parallel to  $EF$ ,  $PR$  will be perpendicular to  $AB$  (Prop. XX. Cor. 1.); and since  $CD$  is parallel to  $EF$ ,  $PR$  will for a like reason be perpendicular to  $CD$ . Hence  $AB$  and  $CD$  are perpendicular to the same straight line; hence they are parallel (Prop. XVIII.).

PROPOSITION XXIII. THEOREM.

*Two parallels are every where equally distant.*

Two parallels  $AB$ ,  $CD$ , being given, if through two points  $E$  and  $F$ , assumed at pleasure, the straight lines  $EG$ ,  $FH$ , be drawn perpendicular to  $AB$ , these straight lines will at the same time be perpendicular to  $CD$  (Prop. XX. Cor. 1.): and we are now to show that they will be equal to each other.

If  $GF$  be drawn, the angles  $GFE$ ,  $FGH$ , considered in reference to the parallels  $AB$ ,  $CD$ , will be alternate angles, and therefore equal to each other (Prop. XX. Cor. 2.). Also, the straight lines  $EG$ ,  $FH$ , being perpendicular to the same straight line  $AB$ , are parallel (Prop. XVIII.); and the angles  $EGF$ ,  $GFH$ , considered in reference to the parallels  $EG$ ,  $FH$ , will be alternate angles, and therefore equal. Hence the two triangles  $EFG$ ,  $FGH$ , have a common side, and two adjacent angles in each equal; hence these triangles are equal (Prop. VI.); therefore, the side  $EG$ , which measures the distance of the parallels  $AB$  and  $CD$  at the point  $E$ , is equal to the side  $FH$ , which measures the distance of the same parallels at the point  $F$ .

## PROPOSITION XXIV. THEOREM.

*If two angles have their sides parallel and lying in the same direction, the two angles will be equal.*

Let  $BAC$  and  $DEF$  be the two angles, having  $AB$  parallel to  $ED$ , and  $AC$  to  $EF$ ; then will the angles be equal.

For, produce  $DE$ , if necessary, till it meets  $AC$  in  $G$ . Then, since  $EF$  is parallel to  $GC$ , the angle  $DEF$  is equal to  $DGC$  (Prop. XX. Cor. 3.); and since  $DG$  is parallel to  $AB$ , the angle  $DGC$  is equal to  $BAC$ ; hence the angle  $DEF$  is equal to  $BAC$  (Ax. 1.).

*Scholium.* The restriction of this proposition to the case where the side  $EF$  lies in the same direction with  $AC$ , and  $ED$  in the same direction with  $AB$ , is necessary, because if  $FE$  were produced towards  $H$ , the angle  $DEH$  would have its sides parallel to those of the angle  $BAC$ , but would not be equal to it. In that case,  $DEH$  and  $BAC$  would be together equal to two right angles. For,  $DEH + DEF$  is equal to two right angles (Prop. I.); but  $DEF$  is equal to  $BAC$ : hence,  $DEH + BAC$  is equal to two right angles.

## PROPOSITION XXV. THEOREM.

*In every triangle the sum of the three angles is equal to two right angles.*

Let  $ABC$  be any triangle: then will the angle  $C + A + B$  be equal to two right angles.

For, produce the side  $CA$  towards  $D$ , and at the point  $A$ , draw  $AE$  parallel to  $BC$ . Then, since  $AE$ ,  $CB$ , are parallel, and  $CAD$  cuts them, the exterior angle  $DAE$  will be equal to its interior opposite one  $ACB$  (Prop. XX. Cor. 3.); in like manner, since  $AE$ ,  $CB$ , are parallel, and  $AB$  cuts them, the alternate angles  $ABC$ ,  $BAE$ , will be equal: hence the three angles of the triangle  $ABC$  make up the same sum as the three angles  $CAB$ ,  $BAE$ ,  $EAD$ ; hence, the sum of the three angles is equal to two right angles (Prop. I.).

*Cor. 1.* Two angles of a triangle being given, or merely their sum, the third will be found by subtracting that sum from two right angles.

*Cor. 2.* If two angles of one triangle are respectively equal to two angles of another, the third angles will also be equal, and the two triangles will be mutually equiangular.

*Cor. 3.* In any triangle there can be but one right angle : for if there were two, the third angle must be nothing. Still less, can a triangle have more than one obtuse angle.

*Cor. 4.* In every right angled triangle, the sum of the two acute angles is equal to one right angle.

*Cor. 5.* Since every equilateral triangle is also equiangular (Prop. XI. Cor.), each of its angles will be equal to the third part of two right angles ; so that, if the right angle is expressed by unity, the angle of an equilateral triangle will be expressed by  $\frac{2}{3}$ .

*Cor. 6.* In every triangle ABC, the exterior angle BAD is equal to the sum of the two interior opposite angles B and C. For, AE being parallel to BC, the part BAE is equal to the angle B, and the other part DAE is equal to the angle C.

#### PROPOSITION XXVI. THEOREM.

*The sum of all the interior angles of a polygon, is equal to two right angles, taken as many times less two, as the figure has sides.*

Let ABCDEFG be the proposed polygon. If from the vertex of any one angle A, diagonals AC, AD, AE, AF, be drawn to the vertices of all the opposite angles, it is plain that the polygon will be divided into five triangles, if it has seven sides ; into six triangles, if it has eight ; and, in general, into as many triangles, less two, as the polygon has sides ; for, these triangles may be considered as having the point A for a common vertex, and for bases, the several sides of the polygon, excepting the two sides which form the angle A. It is evident, also, that the sum of all the angles in these triangles does not differ from the sum of all the angles in the polygon : hence the sum of all the angles of the polygon is equal to two right angles, taken as many times as there are triangles in the figure ; in other words, as there are units in the number of sides diminished by two.

*Cor. 1.* The sum of the angles in a quadrilateral is equal to two right angles multiplied by  $4-2$ , which amounts to four

right angles : hence, if all the angles of a quadrilateral are equal, each of them will be a right angle ; a conclusion which sanctions the seventeenth Definition, where the four angles of a quadrilateral are asserted to be right angles, in the case of the rectangle and the square.

*Cor. 2.* The sum of the angles of a pentagon is equal to two right angles multiplied by  $5-2$ , which amounts to six right angles : hence, when a pentagon is equiangular, each angle is equal to the fifth part of six right angles, or to  $\frac{6}{5}$  of one right angle.

*Cor. 3.* The sum of the angles of a hexagon is equal to  $2 \times (6-2)$ , or eight right angles ; hence in the equiangular hexagon, each angle is the sixth part of eight right angles, or  $\frac{4}{3}$  of one.

*Scholium.* When this proposition is applied to polygons which have *re-entrant* angles, each re-entrant angle must be regarded as greater than two right angles. But to avoid all ambiguity, we shall henceforth limit our reasoning to polygons with *salient* angles, which might otherwise be named *convex polygons*. Every convex polygon is such that a straight line, drawn at pleasure, cannot meet the contour of the polygon in more than two points.

#### PROPOSITION XXVII. THEOREM.

*If the sides of any polygon be produced out, in the same direction, the sum of the exterior angles will be equal to four right angles.*

Let the sides of the polygon ABCD-FG, be produced, in the same direction ; then will the sum of the exterior angles  $a+b+c+d+f+g$ , be equal to four right angles.

For, each interior angle, plus its exterior angle, as  $A+a$ , is equal to two right angles (Prop. I.). But there are as many exterior as interior angles, and as many of each as there are sides of the polygon : hence, the sum of all the interior and exterior angles is equal to twice as many right angles as the polygon has sides. Again, the sum of all the interior angles is equal to two right angles, taken as many times, less two, as the polygon has sides (Prop. XXVI.) ; that is, equal to twice as many right angles as the figure has sides, wanting four right angles. Hence, the interior angles plus four right

angles, is equal to twice as many right angles as the polygon has sides, and consequently, equal to the sum of the interior angles plus the exterior angles. Taking from each the sum of the interior angles, and there remains the exterior angles, equal to four right angles.

PROPOSITION XXVIII. THEOREM.

*In every parallelogram, the opposite sides and angles are equal.*

Let ABCD be a parallelogram: then will  $AB=DC$ ,  $AD=BC$ ,  $A=C$ , and  $ADC=ABC$ .

For, draw the diagonal BD. The triangles ABD, DBC, have a common side BD; and since AD, BC, are parallel, they have also the angle  $ADB=DBC$ , (Prop. XX. Cor. 2.); and since AB, CD, are parallel, the angle  $ABD=BDC$ : hence the two triangles are equal (Prop. VI.); therefore the side AB, opposite the angle ADB, is equal to the side DC, opposite the equal angle DBC; and the third sides AD, BC, are equal: hence the opposite sides of a parallelogram are equal.

Again, since the triangles are equal, it follows that the angle A is equal to the angle C; and also that the angle ADC composed of the two ADB, BDC, is equal to ABC, composed of the two equal angles DBC, ABD: hence the opposite angles of a parallelogram are also equal.

*Cor.* Two parallels AB, CD, included between two other parallels AD, BC, are equal; and the diagonal DB divides the parallelogram into two equal triangles.

PROPOSITION XXIX. THEOREM.

*If the opposite sides of a quadrilateral are equal, each to each, the equal sides will be parallel, and the figure will be a parallelogram.*

Let ABCD be a quadrilateral, having its opposite sides respectively equal, viz.  $AB=DC$ , and  $AD=BC$ ; then will these sides be parallel, and the figure be a parallelogram.

For, having drawn the diagonal BD, the triangles ABD, DBC, have all the sides of the one equal to

the corresponding sides of the other; therefore they are equal, and the angle  $ADB$ , opposite the side  $AB$ , is equal to  $DBC$ , opposite  $CD$  (Prop. X.); therefore, the side  $AD$  is parallel to  $BC$  (Prop. XIX. Cor. 1.). For a like reason  $AB$  is parallel to  $CD$ : therefore the quadrilateral  $ABCD$  is a parallelogram.

PROPOSITION XXX. THEOREM.

*If two opposite sides of a quadrilateral are equal and parallel, the remaining sides will also be equal and parallel, and the figure will be a parallelogram.*

Let  $ABCD$  be a quadrilateral, having the sides  $AB$ ,  $CD$ , equal and parallel; then will the figure be a parallelogram.

For, draw the diagonal  $DB$ , dividing the quadrilateral into two triangles. Then, since  $AB$  is parallel to  $DC$ , the alternate angles  $ABD$ ,  $BDC$ , are equal (Prop. XX. Cor. 2.); moreover, the side  $DB$  is common, and the side  $AB = DC$ ; hence the triangle  $ABD$  is equal to the triangle  $DBC$  (Prop. V.); therefore, the side  $AD$  is equal to  $BC$ , the angle  $ADB = DBC$ , and consequently  $AD$  is parallel to  $BC$ ; hence the figure  $ABCD$  is a parallelogram.

PROPOSITION XXXI. THEOREM.

*The two diagonals of a parallelogram divide each other into equal parts, or mutually bisect each other.*

Let  $ABCD$  be a parallelogram,  $AC$  and  $DB$  its diagonals, intersecting at  $E$ , then will  $AE = EC$ , and  $DE = EB$ .

Comparing the triangles  $ADE$ ,  $CEB$ , we find the side  $AD = CB$  (Prop. XXVIII.), the angle  $ADE = CBE$ , and the angle  $DAE = ECB$  (Prop. XX. Cor. 2.); hence those triangles are equal (Prop. VI.); hence,  $AE$ , the side opposite the angle  $ADE$ , is equal to  $EC$ , opposite  $EBC$ ; hence also  $DE$  is equal to  $EB$ .

*Scholium.* In the case of the rhombus, the sides  $AB$ ,  $BC$  being equal, the triangles  $AEB$ ,  $EBC$ , have all the sides of the one equal to the corresponding sides of the other, and are therefore equal: whence it follows that the angles  $AEB$ ,  $BEC$ , are equal, and therefore, that the two diagonals of a rhombus cut each other at right angles.

## BOOK II.

## OF RATIOS AND PROPORTIONS.

*Definitions.*

1. *Ratio* is the quotient arising from dividing one quantity by another quantity of the same kind. Thus, if A and B represent quantities of the same kind, the ratio of A to B is expressed by  $\frac{B}{A}$ .

The ratios of magnitudes may be expressed by numbers, either exactly or approximatively; and in the latter case, the approximation may be brought nearer to the true ratio than any assignable difference.

Thus, of two magnitudes, one of them may be considered to be divided into some number of equal parts, each of the same kind as the whole, and one of those parts being considered as an unit of measure, the magnitude may be expressed by the number of units it contains. If the other magnitude contain a certain number of those units, it also may be expressed by the number of its units, and the two quantities are then said to be *commensurable*.

If the second magnitude do not contain the measuring unit an exact number of times, there may perhaps be a smaller unit which will be contained an exact number of times in each of the magnitudes. But if there is no unit of an *assignable* value, which shall be contained an exact number of times in each of the magnitudes, the magnitudes are said to be *incommensurable*.

It is plain, however, that the unit of measure, repeated as many times as it is contained in the second magnitude, would always differ from the second magnitude by a quantity less than the unit of measure, since the remainder is always less than the divisor. Now, since the unit of measure may be made as small as we please, it follows, that magnitudes may be represented by numbers to any degree of exactness, or they will differ from their numerical representatives by less than any assignable quantity.

Therefore, of two magnitudes, A and B, we may conceive A to be divided into M number of units, each equal to A': then  $A = M \times A'$ ; let B be divided into N number of equal units, each equal to A'; then  $B = N \times A'$ ; M and N being integral numbers. Now the ratio of A to B, will be the same as the ratio of  $M \times A'$  to  $N \times A'$ ; that is the same as the ratio of M to N, since A' is a common unit.

In the same manner, the ratio of any other two magnitudes C and D may be expressed by  $P \times C'$  to  $Q \times C'$ , P and Q being also integral numbers, and their ratio will be the same as that of P to Q.

2. If there be four magnitudes A, B, C, and D, having such values that  $\frac{B}{A}$  is equal to  $\frac{D}{C}$ , then A is said to have the same *ratio* to B, that C has to D, or the ratio of A to B is *equal* to the ratio of C to D. When four quantities have this relation to each other, they are said to be in *proportion*.

To indicate that the ratio of A to B is equal to the ratio of C to D, the quantities are usually written thus,  $A : B :: C : D$ , and read, A is to B as C is to D. The quantities which are compared together are called the *terms* of the proportion. The first and last terms are called the *two extremes*, and the second and third terms, the two means.

3. Of four proportional quantities, the first and third are called the *antecedents*, and the second and fourth the *consequents*; and the last is said to be a *fourth proportional* to the other three taken in order.

4. Three quantities are in proportion, when the first has the same ratio to the second, that the second has to the third; and then the middle term is said to be a mean proportional between the other two.

5. Magnitudes are said to be in proportion by *inversion*, or *inversely*, when the consequents are taken as antecedents, and the antecedents as consequents.

6. Magnitudes are in proportion by *alternation*, or alternately, when antecedent is compared with antecedent, and consequent with consequent.

7. Magnitudes are in proportion by *composition*, when the sum of the antecedent and consequent is compared either with antecedent or consequent.

8. Magnitudes are said to be in proportion by *division*, when the difference of the antecedent and consequent is compared either with antecedent or consequent.

9. Equimultiples of two quantities are the products which arise from multiplying the quantities by the same number: thus,  $m \times A$ ,  $m \times B$ , are equimultiples of A and B, the common multiplier being  $m$ .

10. Two quantities A and B are said to be *reciprocally proportional*, or *inversely proportional*, when one increases in the same ratio as the other diminishes. In such case, either of them is equal to a constant quantity divided by the other, and their product is constant.

## PROPOSITION I. THEOREM.

*When four quantities are in proportion, the product of the two extremes is equal to the product of the two means*

Let  $A, B, C, D$ , be four quantities in proportion, and  $M : N :: P : Q$  be their numerical representatives; then will  $M \times Q = N \times P$ ; for since the quantities are in proportion  $\frac{N}{M} = \frac{Q}{P}$  therefore  $N = M \times \frac{Q}{P}$ , or  $N \times P = M \times Q$ .

*Cor.* If there are three proportional quantities (Def. 4.), the product of the extremes will be equal to the square of the mean.

## PROPOSITION II. THEOREM.

*If the product of two quantities be equal to the product of two other quantities, two of them will be the extremes and the other two the means of a proportion.*

Let  $M \times Q = N \times P$ ; then will  $M : N :: P : Q$ .

For, if  $P$  have not to  $Q$  the ratio which  $M$  has to  $N$ , let  $P$  have to  $Q'$ , a number greater or less than  $Q$ , the same ratio that  $M$  has to  $N$ ; that is, let  $M : N :: P : Q'$ ; then  $M \times Q' =$

$N \times P$  (Prop. I.) : hence,  $Q' = \frac{N \times P}{M}$ ; but  $Q = \frac{N \times P}{M}$ ; con-

sequently,  $Q = Q'$  and the four quantities are proportional; that is,  $M : N :: P : Q$ .

## PROPOSITION III. THEOREM.

*If four quantities are in proportion, they will be in proportion when taken alternately.*

Let  $M, N, P, Q$ , be the numerical representatives of four quantities in proportion; so that

$M : N :: P : Q$ , then will  $M : P :: N : Q$ .

Since  $M : N :: P : Q$ , by supposition,  $M \times Q = N \times P$ ; therefore,  $M$  and  $Q$  may be made the extremes, and  $N$  and  $P$  the means of a proportion (Prop. II.); hence,  $M : P :: N : Q$ .

## PROPOSITION IV. THEOREM.

*If there be four proportional quantities, and four other proportional quantities, having the antecedents the same in both, the consequents will be proportional.*

Let  $M : N :: P : Q$   
 and  $M : R :: P : S$   
 then will  $N : Q :: R : S$

For, by alternation  $M : P :: N : Q$ , or  $\frac{P}{M} = \frac{Q}{N}$

and  $M : P :: R : S$ , or  $\frac{P}{M} = \frac{S}{R}$

hence  $\frac{Q}{N} = \frac{S}{R}$ ; or  $N : Q :: R : S$ .

*Cor.* If there be two sets of proportionals, having an antecedent and consequent of the first, equal to an antecedent and consequent of the second, the remaining terms will be proportional.

## PROPOSITION V. THEOREM.

*If four quantities be in proportion, they will be in proportion when taken inversely.*

Let  $M : N :: P : Q$ ; then will  
 $N : M :: Q : P$ .

For, from the first proportion we have  $M \times Q = N \times P$ , or  
 $N \times P = M \times Q$ .

But the products  $N \times P$  and  $M \times Q$  are the products of the extremes and means of the four quantities  $N, M, Q, P$ , and these products being equal,

$N : M :: Q : P$  (Prop. II.).

## PROPOSITION VI. THEOREM.

*If four quantities are in proportion, they will be in proportion by composition, or division.*

Let, as before,  $M, N, P, Q$ , be the numerical representatives of the four quantities, so that

$M : N :: P : Q$  ; then will

$$M \pm N : M :: P \pm Q : P.$$

For, from the first proportion, we have

$$M \times Q = N \times P, \text{ or } N \times P = M \times Q ;$$

Add each of the members of the last equation to, or subtract it from  $M.P$ , and we shall have,

$$M.P \pm N.P = M.P \pm M.Q ; \text{ or}$$

$$(M \pm N) \times P = (P \pm Q) \times M.$$

But  $M \pm N$  and  $P$ , may be considered the two extremes, and  $P \pm Q$  and  $M$ , the two means of a proportion : hence,

$$M \pm N : M :: P \pm Q : P.$$

#### PROPOSITION VII. THEOREM.

*Equimultiples of any two quantities, have the same ratio as the quantities themselves.*

Let  $M$  and  $N$  be any two quantities, and  $m$  any integral number ; then will

$$m. M : m. N :: M : N. \text{ For}$$

$m. M \times N = m. N \times M$ , since the quantities in each member are the same ; therefore, the quantities are proportional (Prop. II.) ; or

$$m. M : m. N :: M : N.$$

#### PROPOSITION VIII. THEOREM.

*Of four proportional quantities, if there be taken any equimultiples of the two antecedents, and any equimultiples of the two consequents, the four resulting quantities will be proportional.*

Let  $M, N, P, Q$ , be the numerical representatives of four quantities in proportion ; and let  $m$  and  $n$  be any numbers whatever, then will

$$m. M : n. N :: m. P : n. Q.$$

For, since  $M : N :: P : Q$ , we have  $M \times Q = N \times P$  ; hence,  $m. M \times n. Q = n. N \times m. P$ , by multiplying both members of the equation by  $m \times n$ . But  $m. M$  and  $n. Q$ , may be regarded as the two extremes, and  $n. N$  and  $m. P$ , as the means of a proportion ; hence,  $m. M : n. N :: m. P : n. Q$ .

## BOOK II.

### PROPOSITION IX. THEOREM.

*Of four proportional quantities, if the two consequents be either augmented or diminished by quantities which have the same ratio as the antecedents, the resulting quantities and the antecedents will be proportional.*

|            |   |
|------------|---|
| Let        | $M : N :: P : Q$ , and let also                         |
|            | $M : P :: m : n$ , then will                            |
|            | $M : P :: N \pm m : Q \pm n$ .                          |
| For, since | $M : N :: P : Q$ , $M \times Q = N \times P$ .          |
| And since  | $M : P :: m : n$ , $M \times n = P \times m$            |
| Therefore, | $M \times Q \pm M \times n = N \times P \pm P \times m$ |
| or,        | $M \times (Q \pm n) = P \times (N \pm m) :$             |
| hence      | $M : P :: N \pm m : Q \pm n$ (Prop. II.).               |

### PROPOSITION X. THEOREM.

*If any number of quantities are proportionals, any one antecedent will be to its consequent, as the sum of all the antecedents to the sum of the consequents.*

|              |  |
|--------------|--|
| Let          | $M : N :: P : Q :: R : S$ , &c. then will            |
|              | $M : N :: \overline{M+P+R} : \overline{N+Q+S}$       |
| For, since   | $M : N :: P : Q$ , we have $M \times Q = N \times P$ |
| And since    | $M : N :: R : S$ , we have $M \times S = N \times R$ |
| Add          | $M \times N = M \times N$                            |
| and we have, | $M.N + M.Q + M.S = M.N + N.P + N.R$                  |
| or           | $M \times (N + Q + S) = N \times (M + P + R)$        |
| therefore,   | $M : N :: \overline{M+P+R} : \overline{N+Q+S}$ .     |

### PROPOSITION XI. THEOREM.

*If two magnitudes be each increased or diminished by like parts of each, the resulting quantities will have the same ratio as the magnitudes themselves.*

Let  $M$  and  $N$  be any two magnitudes, and  $\frac{M}{m}$  and  $\frac{N}{m}$  be like parts of each : then will

$$M : N :: M \pm \frac{M}{m} : N \pm \frac{N}{m}$$

For, it is obvious that  $M \times (N \pm \frac{N}{m}) = N \times (M \pm \frac{M}{m})$  since each is equal to  $M.N \pm \frac{N.M}{m}$ . Consequently, the four quantities are proportional (Prop. II.).

PROPOSITION XII. THEOREM.

*If four quantities are proportional, their squares or cubes will also be proportional.*

Let  $M : N : P : Q$ ,  
 then will  $M^2 : N^2 :: P^2 : Q^2$   
 and  $M^3 : N^3 :: P^3 : Q^3$   
 For,  $M \times Q = N \times P$ , since  $M : N :: P : Q$   
 or,  $M^2 \times Q^2 = N^2 \times P^2$ , by squaring both members,  
 and  $M^3 \times Q^3 = N^3 \times P^3$ , by cubing both members ;  
 therefore,  $M^2 : N^2 :: P^2 : Q^2$   
 and  $M^3 : N^3 :: P^3 : Q^3$

*Cor.* In the same way it may be shown that like powers or roots of proportional quantities are proportionals.

PROPOSITION XIII. THEOREM.

*If there be two sets of proportional quantities, the products of the corresponding terms will be proportional.*

Let  $M : N :: P : Q$   
 and  $R : S :: T : V$   
 then will  $M \times R : N \times S :: P \times T : Q \times V$   
 For since  $M \times Q = N \times P$   
 and  $R \times V = S \times T$ , we shall have  
 $M \times Q \times R \times V = N \times P \times S \times T$   
 or  $\overline{M \times R \times Q \times V} = \overline{N \times S \times P \times T}$   
 therefore,  $\overline{M \times R} : \overline{N \times S} :: \overline{P \times T} : \overline{Q \times V}$

## BOOK III.

## THE CIRCLE, AND THE MEASUREMENT OF ANGLES.

*Definitions.*

1. The *circumference of a circle* is a curved line, all the points of which are equally distant from a point within, called the *centre*.

The *circle* is the space terminated by this curved line.\*

2. Every straight line, CA, CE, CD, drawn from the centre to the circumference, is called a *radius* or *semidiameter*; every line which, like AB, passes through the centre, and is terminated on both sides by the circumference, is called a *diameter*.

From the definition of a circle, it follows that all the radii are equal; that all the diameters are equal also, and each double of the radius.

3. A portion of the circumference, such as FHG, is called an *arc*.

The *chord*, or *subtense* of an arc, is the straight line FG, which joins its two extremities.†

4. A *segment* is the surface or portion of a circle, included between an arc and its chord.

5. A *sector* is the part of the circle included between an arc DE, and the two radii CD, CE, drawn to the extremities of the arc.

6. A *straight line* is said to be *inscribed in a circle*, when its extremities are in the circumference, as AB.

An *inscribed angle* is one which, like BAC, has its vertex in the circumference, and is formed by two chords.

\* *Note.* In common language, the circle is sometimes confounded with its circumference: but the correct expression may always be easily recurred to if we bear in mind that the circle is a surface which has length and breadth, while the circumference is but a line.

† *Note.* In all cases, the same chord FG belongs to two arcs, FGH. FEG, and consequently also to two segments: but the smaller one is always meant, unless the contrary is expressed.

## GEOMETRY.

An *inscribed triangle* is one which, like BAC, has its three angular points in the circumference.

And, generally, an *inscribed figure* is one, of which all the angles have their vertices in the circumference. The circle is then said to *circumscribe* such a figure.

7. A *secant* is a line which meets the circumference in two points, and lies partly within and partly without the circle. AB is a secant.

8. A *tangent* is a line which has but one point in common with the circumference. CD is a tangent.

The point M, where the tangent touches the circumference, is called the *point of contact*.

In like manner, two circumferences *touch* each other when they have but one point in common.

9. A polygon is *circumscribed about a circle*, when all its sides are tangents to the circumference: in the same case, the circle is said to be *inscribed in the polygon*.

### PROPOSITION I. THEOREM.

*Every diameter divides the circle and its circumference into two equal parts.*

Let AEDF be a circle, and AB a diameter. Now, if the figure AEB be applied to AFB, their common base AB retaining its position, the curve line AEB must fall exactly on the curve line AFB, otherwise there would, in the one or the other, be points unequally distant from the centre, which is contrary to the definition of a circle.

## PROPOSITION II. THEOREM.

*Every chord is less than the diameter.*

Let  $AD$  be any chord. Draw the radii  $CA$ ,  $CD$ , to its extremities. We shall then have  $AD < AC + CD$  (Book I. Prop. VII.\*); or  $AD < AB$ .

*Cor.* Hence the greatest line which can be inscribed in a circle is its diameter.

## PROPOSITION III. THEOREM.

*A straight line cannot meet the circumference of a circle in more than two points.*

For, if it could meet it in three, those three points would be equally distant from the centre; and hence, there would be three equal straight lines drawn from the same point to the same straight line, which is impossible (Book I. Prop. XV. Cor. 2.).

## PROPOSITION IV. THEOREM.

*In the same circle, or in equal circles, equal arcs are subtended by equal chords; and, conversely, equal chords subtend equal arcs.*

---

*Note.* When reference is made from one proposition to another, in the same Book, the number of the proposition referred to is alone given; but when the proposition is found in a different Book, the number of the Book is also given.

If the radii  $AC$ ,  $EO$ , are equal, and also the arcs  $AMD$ ,  $ENG$ ; then the chord  $AD$  will be equal to the chord  $EG$ .

For, since the diameters  $AB$ ,  $EF$ , are equal, the semicircle  $AMDB$  may be applied exactly to the semicircle  $ENGF$ , and the curve line  $AMDB$  will coincide entirely with the curve line  $ENGF$ . But the part  $AMD$  is equal to the part  $ENG$ , by hypothesis; hence, the point  $D$  will fall on  $G$ ; therefore, the chord  $AD$  is equal to the chord  $EG$ .

Conversely, supposing again the radii  $AC$ ,  $EO$ , to be equal, if the chord  $AD$  is equal to the chord  $EG$ , the arcs  $AMD$ ,  $ENG$  will also be equal.

For, if the radii  $CD$ ,  $OG$ , be drawn, the triangles  $ACD$ ,  $EOG$ , will have all their sides equal, each to each, namely,  $AC=EO$ ,  $CD=OG$ , and  $AD=EG$ ; hence the triangles are themselves equal; and, consequently, the angle  $ACD$  is equal  $EOG$  (Book I. Prop. X.). Now, placing the semicircle  $ADB$  on its equal  $EGF$ , since the angles  $ACD$ ,  $EOG$ , are equal, it is plain that the radius  $CD$  will fall on the radius  $OG$ , and the point  $D$  on the point  $G$ ; therefore the arc  $AMD$  is equal to the arc  $ENG$ .

#### PROPOSITION V. THEOREM.

*In the same circle, or in equal circles, a greater arc is subtended by a greater chord, and conversely, the greater chord subtends the greater arc.*

Let the arc  $AH$  be greater than the arc  $AD$ ; then will the chord  $AH$  be greater than the chord  $AD$ .

For, draw the radii  $CD$ ,  $CH$ . The two sides  $AC$ ,  $CH$ , of the triangle  $ACH$  are equal to the two  $AC$ ,  $CD$ , of the triangle  $ACD$ , and the angle  $ACH$  is greater than  $ACD$ ; hence, the third side  $AH$  is greater than the third side  $AD$  (Book I. Prop. IX.); therefore the chord, which subtends the greater arc, is the greater. Conversely, if the chord  $AH$  is greater than  $AD$ , it will follow, on comparing the same triangles, that the angle  $ACH$  is

greater than  $ACD$  (Bk. I. Prop. IX. Sch.); and hence that the arc  $AH$  is greater than  $AD$ ; since the whole is greater than its part.

*Scholium.* The arcs here treated of are each less than the semicircumference. If they were greater, the reverse property would have place; for, as the arcs increase, the chords would diminish, and conversely. Thus, the arc  $AKBD$  is greater than  $AKBH$ , and the chord  $AD$ , of the first, is less than the chord  $AH$  of the second.

### PROPOSITION VI. THEOREM.

*The radius which is perpendicular to a chord, bisects the chord, and bisects also the subtended arc of the chord.*

Let  $AB$  be a chord, and  $CG$  the radius perpendicular to it: then will  $AD = DB$ , and the arc  $AG = GB$ .

For, draw the radii  $CA$ ,  $CB$ . Then the two right angled triangles  $ADC$ ,  $CDB$ , will have  $AC = CB$ , and  $CD$  common; hence,  $AD$  is equal to  $DB$  (Book I. Prop. XVII.).

Again, since  $AD$ ,  $DB$ , are equal,  $CG$  is a perpendicular erected from the middle of  $AB$ ; hence every point of this perpendicular must be equally distant from its two extremities  $A$  and  $B$  (Book I. Prop. XVI.). Now,  $G$  is one of these points; therefore  $AG$ ,  $BG$ , are equal. But if the chord  $AG$  is equal to the chord  $GB$ , the arc  $AG$  will be equal to the arc  $GB$  (Prop. IV.); hence, the radius  $CG$ , at right angles to the chord  $AB$ , divides the arc subtended by that chord into two equal parts at the point  $G$ .

*Scholium.* The centre  $C$ , the middle point  $D$ , of the chord  $AB$ , and the middle point  $G$ , of the arc subtended by this chord, are three points of the same line perpendicular to the chord. But two points are sufficient to determine the position of a straight line; hence every straight line which passes through two of the points just mentioned, will necessarily pass through the third, and be perpendicular to the chord.

It follows, likewise, that *the perpendicular raised from the middle of a chord passes through the centre of the circle, and through the middle of the arc subtended by that chord.*

For, this perpendicular is the same as the one let fall from the centre on the same chord, since both of them pass through the centre and middle of the chord.

## PROPOSITION VII. THEOREM.

*Through three given points not in the same straight line, one circumference may always be made to pass, and but one.*

Let  $A$ ,  $B$ , and  $C$ , be the given points.

Draw  $AB$ ,  $BC$ , and bisect these straight lines by the perpendiculars  $DE$ ,  $FG$ : we say first, that  $DE$  and  $FG$ , will meet in some point  $O$ .

For, they must necessarily cut each other, if they are not parallel.

Now, if they were parallel, the line  $AB$ , which is perpendicular to  $DE$ , would also be perpendicular to  $FG$ , and the angle  $K$  would be a right angle (Book I. Prop. XX. Cor. 1.). But  $BK$ , the prolongation of  $BD$ , is a different line from  $BF$ , because the three points  $A$ ,  $B$ ,  $C$ , are not in the same straight line; hence there would be two perpendiculars,  $BF$ ,  $BK$ , let fall from the same point  $B$ , on the same straight line, which is impossible (Book I. Prop. XIV.) ; hence  $DE$ ,  $FG$ , will always meet in some point  $O$ .

And moreover, this point  $O$ , since it lies in the perpendicular  $DE$ , is equally distant from the two points,  $A$  and  $B$  (Book I. Prop. XVI.) ; and since the same point  $O$  lies in the perpendicular  $FG$ , it is also equally distant from the two points  $B$  and  $C$ : hence the three distances  $OA$ ,  $OB$ ,  $OC$ , are equal; therefore the circumference described from the centre  $O$ , with the radius  $OB$ , will pass through the three given points  $A$ ,  $B$ ,  $C$ .

We have now shown that one circumference can always be made to pass through three given points, not in the same straight line: we say farther, that but one can be described through them.

For, if there were a second circumference passing through the three given points  $A$ ,  $B$ ,  $C$ , its centre could not be out of the line  $DE$ , for then it would be unequally distant from  $A$  and  $B$  (Book I. Prop. XVI.); neither could it be out of the line  $FG$ , for a like reason; therefore, it would be in both the lines  $DE$ ,  $FG$ . But two straight lines cannot cut each other in more than one point; hence there is but one circumference which can pass through three given points.

*Cor.* Two circumferences cannot meet in more than two points; for, if they have three common points, there would be two circumferences passing through the same three points; which has been shown by the proposition to be impossible.

## PROPOSITION VIII. THEOREM.

*Two equal chords are equally distant from the centre ; and of two unequal chords, the less is at the greater distance from the centre.*

*First.* Suppose the chord  $AB = DE$ . Bisect these chords by the perpendiculars  $CF$ ,  $CG$ , and draw the radii  $CA$ ,  $CD$ .

In the right angled triangles  $CAF$ ,  $DCG$ , the hypotenuses  $CA$ ,  $CD$ , are equal ; and the side  $AF$ , the half of  $AB$ , is equal to the side  $DG$ , the half of  $DE$  : hence the triangles are equal, and  $CF$  is equal to  $CG$  (Book I. Prop. XVII.) ; hence, the two equal chords  $AB$ ,  $DE$ , are equally distant from the centre.

*Secondly* Let the chord  $AH$  be greater than  $DE$ . The arc  $AKH$  will be greater than  $DME$  (Prop. V.) : cut off from the former, a part  $ANB$ , equal to  $DME$  ; draw the chord  $AB$ , and let fall  $CF$  perpendicular to this chord, and  $CI$  perpendicular to  $AH$ . It is evident that  $CF$  is greater than  $CO$ , and  $CO$  than  $CI$  (Book I. Prop. XV.) ; therefore,  $CF$  is still greater than  $CI$ . But  $CF$  is equal to  $CG$ , because the chords  $AB$ ,  $DE$ , are equal : hence we have  $CG > CI$  ; hence of two unequal chords, the less is the farther from the centre.

## PROPOSITION IX. THEOREM.

*A straight line perpendicular to a radius, at its extremity, is a tangent to the circumference.*

Let  $BD$  be perpendicular to the radius  $CA$ , at its extremity  $A$  ; then will it be tangent to the circumference.

For every oblique line  $CE$ , is longer than the perpendicular  $CA$  (Book I. Prop. XV.) ; hence the point  $E$  is without the circle ; therefore,  $BD$  has no point but  $A$  common to it and the circumference ; consequently  $BD$  is a tangent (Def. 8.).

*Scholium.* At a given point A, only one tangent AD can be drawn to the circumference ; for, if another could be drawn, it would not be perpendicular to the radius CA (Book I. Prop. XIV. Sch.) ; hence in reference to this new tangent, the radius AC would be an oblique line, and the perpendicular let fall from the centre upon this tangent would be shorter than CA ; hence this supposed tangent would enter the circle, and be a secant.

PROPOSITION X. THEOREM.

*Two parallels intercept equal arcs on the circumference.*

There may be three cases.

*First.* If the two parallels are secants, draw the radius CH perpendicular to the chord MP. It will, at the same time be perpendicular to NQ (Book I. Prop. XX. Cor. 1.) ; therefore, the point H will be at once the middle of the arc MHP, and of the arc NHQ (Prop. VI.) ; therefore, we shall have the arc  $MH = HP$ , and the arc  $NH = HQ$  ; and therefore  $MH - NH = HP - HQ$  ; in other words,  $MN = PQ$ .

*Second.* When, of the two parallels AB, DE, one is a secant, the other a tangent, draw the radius CH to the point of contact H ; it will be perpendicular to the tangent DE (Prop. IX.), and also to its parallel MP. But, since CH is perpendicular to the chord MP, the point H must be the middle of the arc MHP (Prop. VI.) ; therefore the arcs MH, HP, included between the parallels AB, DE, are equal.

*Third.* If the two parallels DE, IL, are tangents, the one at H, the other at K, draw the parallel secant AB ; and, from what has just been shown, we shall have  $MH = HP$ ,  $MK = KP$  ; and hence the whole arc  $HMK = HPK$ . It is farther evident that each of these arcs is a semicircumference.

## PROPOSITION XI. THEOREM.

*If two circles cut each other in two points, the line which passes through their centres, will be perpendicular to the chord which joins the points of intersection, and will divide it into two equal parts.*

For, let the line AB join the points of intersection. It will be a common chord to the two circles. Now if a perpendicular

be erected from the middle of this chord, it will pass through each of the two centres C and D (Prop. VI. Sch.). But no more than one straight line can be drawn through two points; hence the straight line, which passes through the centres, will bisect the chord at right angles.

## PROPOSITION XII. THEOREM.

*If the distance between the centres of two circles is less than the sum of the radii, the greater radius being at the same time less than the sum of the smaller and the distance between the centres, the two circumferences will cut each other.*

For, to make an intersection possible, the triangle CAD must be possible. Hence, not only must we have  $CD < AC + AD$ , but also the greater radius  $AD < AC + CD$  (Book I. Prop. VII.). And, whenever the triangle CAD can be constructed, it is plain that the circles described from the centres C and D, will cut each other in A and B.

## PROPOSITION XIII. THEOREM.

*If the distance between the centres of two circles is equal to the sum of their radii, the two circles will touch each other externally.*

Let C and D be the centres at a distance from each other equal to  $CA + AD$ .

The circles will evidently have the point A common, and they will have no other; because, if they had two points common, the distance between their centres must be less than the sum of their radii.

## PROPOSITION XIV. THEOREM.

*If the distance between the centres of two circles is equal to the difference of their radii, the two circles will touch each other internally.*

Let C and D be the centres at a distance from each other equal to  $AD - CA$ .

It is evident, as before, that they will have the point A common; they can have no other; because, if they had, the greater radius AD must be less than the sum of the radius AC and the distance CD between the centres (Prop. XII.); which is contrary to the supposition.

*Cor.* Hence, if two circles touch each other, either externally or internally, their centres and the point of contact will be in the same right line.

*Scholium.* All circles which have their centres on the right line AD. and which pass through the point A, are tangent to each other. For, they have only the point A common, and if through the point A, AE be drawn perpendicular to AD, the straight line AE will be a common tangent to all the circles.

## PROPOSITION XV THEOREM.

*In the same circle, or in equal circles, equal angles having their vertices at the centre, intercept equal arcs on the circumference: and conversely, if the arcs intercepted are equal, the angles contained by the radii will also be equal.*

Let  $C$  and  $C$  be the centres of equal circles, and the angle  $ACB = DCE$ .

*First.* Since the angles  $ACB$ ,  $DCE$ , are equal, they may be placed upon each other; and since their sides are equal, the point  $A$  will evidently fall on  $D$ , and the point  $B$  on  $E$ . But, in that case, the arc  $AB$  must also fall on the arc  $DE$ ; for if the arcs did not exactly coincide, there would, in the one or the other, be points unequally distant from the centre; which is impossible: hence the arc  $AB$  is equal to  $DE$ .

*Secondly.* If we suppose  $AB = DE$ , the angle  $ACB$  will be equal to  $DCE$ . For, if these angles are not equal, suppose  $ACB$  to be the greater, and let  $ACI$  be taken equal to  $DCE$ . From what has just been shown, we shall have  $AI = DE$ : but, by hypothesis,  $AB$  is equal to  $DE$ ; hence  $AI$  must be equal to  $AB$ , or a part to the whole, which is absurd (Ax. 8.): hence, the angle  $ACB$  is equal to  $DCE$ .

## PROPOSITION XVI. THEOREM.

*In the same circle, or in equal circles, if two angles at the centre are to each other in the proportion of two whole numbers, the intercepted arcs will be to each other in the proportion of the same numbers, and we shall have the angle to the angle, as the corresponding arc to the corresponding arc.*

Suppose, for example, that the angles  $ACB$ ,  $DCE$ , are to each other as 7 is to 4; or, which is the same thing, suppose that the angle  $M$ , which may serve as a common measure, is contained 7 times in the angle  $ACB$ , and 4 times in  $DCE$

The seven partial angles  $ACm$ ,  $mCn$ ,  $nCp$ , &c., into which  $ACB$  is divided, being each equal to any of the four partial angles into which  $DCE$  is divided; each of the partial arcs  $Am$ ,  $mn$ ,  $np$ , &c., will be equal to each of the partial arcs  $Dx$ ,  $xy$ , &c. (Prop. XV.). Therefore the whole arc  $AB$  will be to the whole arc  $DE$ , as 7 is to 4. But the same reasoning would evidently apply, if in place of 7 and 4 any numbers whatever were employed; hence, if the ratio of the angles  $ACB$ ,  $DCE$ , can be expressed in whole numbers, the arcs  $AB$ ,  $DE$ , will be to each other as the angles  $ACB$ ,  $DCE$ .

*Scholium.* Conversely, if the arcs,  $AB$ ,  $DE$ , are to each other as two whole numbers, the angles  $ACB$ ,  $DCE$  will be to each other as the same whole numbers, and we shall have  $ACB : DCE :: AB : DE$ . For the partial arcs,  $Am$ ,  $mn$ , &c. and  $Dx$ ,  $xy$ , &c., being equal, the partial angles  $ACm$ ,  $mCn$ , &c. and  $DCx$ ,  $xCy$ , &c. will also be equal.

#### PROPOSITION XVII. THEOREM.

*Whatever be the ratio of two angles, they will always be to each other as the arcs intercepted between their sides; the arcs being described from the vertices of the angles as centres with equal radii.*

Let  $ACB$  be the greater and  $ACD$  the less angle.

Let the less angle be placed on the greater. If the proposition is not true, the angle  $ACB$  will be to the angle  $ACD$  as the arc  $AB$  is to an arc greater or less than  $AD$ . Suppose this arc to be greater, and

let it be represented by  $AO$ ; we shall thus have, the angle  $ACB : \text{angle } ACD :: \text{arc } AB : \text{arc } AO$ . Next conceive the arc

AB to be divided into equal parts, each of which is less than DO ; there will be at least one point of division between D and O ; let I be that point ; and draw CI. The arcs AB, AI, will be to each other as two whole numbers, and by the preceding theorem, we shall have, the angle ACB : angle ACI :: arc AB : arc AI. Comparing these two proportions with each other, we see that the antecedents are the same : hence, the consequents are proportional (Book II. Prop. IV.) ; and thus we find the angle ACD : angle ACI :: arc AO : arc AI. But the arc AO is greater than the arc AI ; hence, if this proportion is true, the angle ACD must be greater than the angle ACI : on the contrary, however, it is less ; hence the angle ACB cannot be to the angle ACD as the arc AB is to an arc greater than AD.

By a process of reasoning entirely similar, it may be shown that the fourth term of the proportion cannot be less than AD ; hence it is AD itself ; therefore we have

$$\text{Angle ACB} : \text{angle ACD} :: \text{arc AB} : \text{arc AD}.$$

*Cor.* Since the angle at the centre of a circle, and the arc intercepted by its sides, have such a connexion, that if the one be augmented or diminished in any ratio, the other will be augmented or diminished in the same ratio, we are authorized to establish the one of those magnitudes as the measure of the other ; and we shall henceforth assume the arc AB as the measure of the angle ACB. It is only necessary that, in the comparison of angles with each other, the arcs which serve to measure them, be described with equal radii, as is implied in all the foregoing propositions.

*Scholium 1.* It appears most natural to measure a quantity by a quantity of the same species ; and upon this principle it would be convenient to refer all angles to the right angle ; which, being made the unit of measure, an acute angle would be expressed by some number between 0 and 1 ; an obtuse angle by some number between 1 and 2. This mode of expressing angles would not, however, be the most convenient in practice. It has been found more simple to measure them by arcs of a circle, on account of the facility with which arcs can be made equal to given arcs, and for various other reasons. At all events, if the measurement of angles by arcs of a circle is in any degree indirect, it is still equally easy to obtain the direct and absolute measure by this method ; since, on comparing the arc which serves as a measure to any angle, with the fourth part of the circumference, we find the ratio of the given angle to a right angle, which is the absolute measure.

*Scholium 2.* All that has been demonstrated in the last three propositions, concerning the comparison of angles with arcs, holds true equally, if applied to the comparison of sectors with arcs; for sectors are not only equal when their angles are so, but are in all respects proportional to their angles; hence, *two sectors*  $ACB$ ,  $ACD$ , *taken in the same circle, or in equal circles, are to each other as the arcs*  $AB$ ,  $AD$ , *the bases of those sectors.* It is hence evident that the arcs of the circle, which serve as a measure of the different angles, are proportional to the different sectors, in the same circle, or in equal circles.

PROPOSITION XVIII. THEOREM.

*An inscribed angle is measured by half the arc included between its sides.*

Let  $BAD$  be an inscribed angle, and let us first suppose that the centre of the circle lies within the angle  $BAD$ . Draw the diameter  $AE$ , and the radii  $CB$ ,  $CD$ .

The angle  $BCE$ , being exterior to the triangle  $ABC$ , is equal to the sum of the two interior angles  $CAB$ ,  $ABC$  (Book I. Prop. XXV. Cor. 6.): but the triangle  $BAC$  being isosceles, the angle  $CAB$  is equal to  $ABC$ ; hence the angle  $BCE$  is double of  $BAC$ . Since  $BCE$  lies at the centre, it is measured by the arc  $BE$ ; hence  $BAC$  will be measured by the half of  $BE$ . For a like reason, the angle  $CAD$  will be measured by the half of  $ED$ ; hence  $BAC + CAD$ , or  $BAD$  will be measured by half of  $BE + ED$ , or of  $BED$ .

Suppose, in the second place, that the centre  $C$  lies without the angle  $BAD$ . Then drawing the diameter  $AE$ , the angle  $BAE$  will be measured by the half of  $BE$ ; the angle  $DAE$  by the half of  $DE$ : hence their difference  $BAD$  will be measured by the half of  $BE$  *minus* the half of  $ED$ , or by the half of  $BD$ .

Hence every inscribed angle is measured by half of the arc included between its sides.

*Cor. 1.* All the angles  $BAC$ ,  $BDC$ ,  $BEC$ , inscribed in the same segment are equal; because they are all measured by the half of the same arc  $BOC$ .

*Cor. 2.* Every angle  $BAD$ , inscribed in a semicircle is a right angle; because it is measured by half the semicircumference  $BOD$ , that is, by the fourth part of the whole circumference.

*Cor. 3.* Every angle  $BAC$ , inscribed in a segment greater than a semicircle, is an acute angle; for it is measured by half of the arc  $BOC$ , less than a semicircumference.

And every angle  $BOC$ , inscribed in a segment less than a semicircle, is an obtuse angle; for it is measured by half of the arc  $BAC$ , greater than a semicircumference.

*Cor. 4.* The opposite angles  $A$  and  $C$ , of an inscribed quadrilateral  $ABCD$ , are together equal to two right angles: for the angle  $BAD$  is measured by half the arc  $BCD$ , the angle  $BCD$  is measured by half the arc  $BAD$ ; hence the two angles  $BAD$ ,  $BCD$ , taken together, are measured by the half of the circumference; hence their sum is equal to two right angles.

#### PROPOSITION XIX. THEOREM.

*The angle formed by two chords, which intersect each other, is measured by half the sum of the arcs included between its sides.*

Let  $AB, CD$ , be two chords intersecting each other at  $E$ : then will the angle  $AEC$ , or  $DEB$ , be measured by half of  $AC + DB$ .

Draw  $AF$  parallel to  $DC$ : then will the arc  $DF$  be equal to  $AC$  (Prop. X.); and the angle  $FAB$  equal to the angle  $DEB$  (Book I. Prop. XX. Cor. 3.). But the angle  $FAB$  is measured by half the arc  $FDB$  (Prop. XVIII.); therefore,  $DEB$  is measured by half of  $FDB$ ; that is, by half of  $DB + DF$ , or half of  $DB + AC$ . In the same manner it might be proved that the angle  $AED$  is measured by half of  $AFD + BC$ .

#### PROPOSITION XX. THEOREM.

*The angle formed by two secants, is measured by half the difference of the arcs included between its sides.*

Let  $AB, AC$ , be two secants: then will the angle  $BAC$  be measured by half the difference of the arcs  $BEC$  and  $DF$ .

Draw  $DE$  parallel to  $AC$ : then will the arc  $EC$  be equal to  $DF$ , and the angle  $BDE$  equal to the angle  $BAC$ . But  $BDE$  is measured by half the arc  $BE$ ; hence,  $BAC$  is also measured by half the arc  $BE$ ; that is, by half the difference of  $BEC$  and  $EC$ , or half the difference of  $BEC$  and  $DF$ .

#### PROPOSITION XXI. THEOREM.

*The angle formed by a tangent and a chord, is measured by half of the arc included between its sides.*

Let  $BE$  be the tangent, and  $AC$  the chord.

From  $A$ , the point of contact, draw the diameter  $AD$ . The angle  $BAD$  is a right angle (Prop. IX.), and is measured by half the semicircumference  $AMD$ ; the angle  $DAC$  is measured by the half of  $DC$ : hence,  $BAD + DAC$ , or  $BAC$ , is measured by the half of  $AMD$  plus the half of  $DC$ , or by half the whole arc  $AMDC$ .

It might be shown, by taking the difference between the angles  $DAE$ ,  $DAC$ , that the angle  $CAE$  is measured by half the arc  $AC$ , included between its sides.

### PROBLEMS RELATING TO THE FIRST AND THIRD BOOKS.

#### PROBLEM I.

*To divide a given straight line into two equal parts.*

Let  $AB$  be the given straight line.

From the points  $A$  and  $B$  as centres, with a radius greater than the half of  $AB$ , describe two arcs cutting each other in  $D$ ; the point  $D$  will be equally distant from  $A$  and  $B$ . Find, in like manner, above or beneath the line  $AB$ , a second point  $E$ , equally distant from the points  $A$  and  $B$ ; through the two points  $D$  and  $E$ , draw the line  $DE$ : it will bisect the line  $AB$  in  $C$ .

For, the two points  $D$  and  $E$ , being each equally distant from the extremities  $A$  and  $B$ , must both lie in the perpendicular raised from the middle of  $AB$  (Book I. Prop. XVI. Cor.). But only one straight line can pass through two given points; hence the line  $DE$  must itself be that perpendicular, which divides  $AB$  into two equal parts at the point  $C$ .

## PROBLEM II.

*At a given point, in a given straight line, to erect a perpendicular to this line.*

Let  $A$  be the given point, and  $BC$  the given line.

Take the points  $B$  and  $C$  at equal distances from  $A$ ; then from the points  $B$  and  $C$  as centres, with a radius greater than  $BA$ , describe two arcs intersecting each other in  $D$ ; draw  $AD$ : it will be the perpendicular required.

For, the point  $D$ , being equally distant from  $B$  and  $C$ , must be in the perpendicular raised from the middle of  $BC$  (Book I. Prop. XVI.); and since two points determine a line,  $AD$  is that perpendicular.

*Scholium.* The same construction serves for making a right angle  $BAD$ , at a given point  $A$ , on a given straight line  $BC$ .

## PROBLEM III.

*From a given point, without a straight line, to let fall a perpendicular on this line.*

Let  $A$  be the point, and  $BD$  the straight line.

From the point  $A$  as a centre, and with a radius sufficiently great, describe an arc cutting the line  $BD$  in the two points  $B$  and  $D$ ; then mark a point  $E$ , equally distant from the points  $B$  and  $D$ , and draw  $AE$ : it will be the perpendicular required.

For, the two points  $A$  and  $E$  are each equally distant from the points  $B$  and  $D$ ; hence the line  $AE$  is a perpendicular passing through the middle of  $BD$  (Book I. Prop. XVI. Cor.).

## PROBLEM IV.

*At a point in a given line, to make an angle equal to a given angle.*

Let  $A$  be the given point,  $AB$  the given line, and  $IKL$  the given angle.

From the vertex  $K$ , as a centre, with any radius, describe the arc  $IL$ , terminating in the two sides of the angle. From the point  $A$  as a centre, with a distance  $AB$ , equal to  $KI$ , describe the indefinite arc  $BO$ ; then take a radius equal to the chord  $LI$ , with which, from the point  $B$  as a centre, describe an arc cutting the indefinite arc  $BO$ , in  $D$ ; draw  $AD$ ; and the angle  $DAB$  will be equal to the given angle  $K$ .

For, the two arcs  $BD$ ,  $LI$ , have equal radii, and equal chords; hence they are equal (Prop. IV.); therefore the angles  $BAD$ ,  $IKL$ , measured by them, are equal.

## PROBLEM V.

*To divide a given arc, or a given angle, into two equal parts.*

*First.* Let it be required to divide the arc  $AEB$  into two equal parts. From the points  $A$  and  $B$ , as centres, with the same radius, describe two arcs cutting each other in  $D$ ; through the point  $D$  and the centre  $C$ , draw  $CD$ : it will bisect the arc  $AB$  in the point  $E$ .

For, the two points  $C$  and  $D$  are each equally distant from the extremities  $A$  and  $B$  of the chord  $AB$ ; hence the line  $CD$  bisects the chord at right angles (Book I. Prop. XVI. Cor.); hence, it bisects the arc  $AB$  in the point  $E$  (Prop. VI.).

*Secondly.* Let it be required to divide the angle  $ACB$  into two equal parts. We begin by describing, from the vertex  $C$  as a centre, the arc  $AEB$ ; which is then bisected as above. It is plain that the line  $CD$  will divide the angle  $ACB$  into two equal parts.

*Scholium.* By the same construction, each of the halves  $AE$ ,  $EB$ , may be divided into two equal parts; and thus, by successive subdivisions, a given angle, or a given arc may be divided into four equal parts, into eight, into sixteen, and so on.

## PROBLEM VI.

*Through a given point, to draw a parallel to a given straight line.*

Let  $A$  be the given point, and  $BC$  the given line.

From the point  $A$  as a centre, with a radius greater than the shortest distance from  $A$  to  $BC$ , describe the indefinite arc  $EO$ ; from the point  $E$  as a centre, with the same radius, describe the arc  $AF$ ; make  $ED = AF$ , and draw  $AD$ : this will be the parallel required.

For, drawing  $AE$ , the alternate angles  $AEF$ ,  $EAD$ , are evidently equal; therefore, the lines  $AD$ ,  $EF$ , are parallel (Book I. Prop. XIX. Cor. 1.).

## PROBLEM VII.

*Two angles of a triangle being given, to find the third.*

Draw the indefinite line  $DEF$ ; at any point as  $E$ , make the angle  $DEC$  equal to one of the given angles, and the angle  $CEH$  equal to the other: the remaining angle  $HEF$  will be the third angle required; because those three angles are together equal to two right angles (Book I. Prop. I and XXV).

## PROBLEM VIII.

*Two sides of a triangle, and the angle which they contain, being given, to describe the triangle.*

Let the lines  $B$  and  $C$  be equal to the given sides, and  $A$  the given angle.

Having drawn the indefinite line  $DE$ , at the point  $D$ , make the angle  $EDF$  equal to the given angle  $A$ ; then take  $DG = B$ ,  $DH = C$ , and draw  $GH$ ;  $DGH$  will be the triangle required (Book I. Prop. V.).

## PROBLEM IX.

*A side and two angles of a triangle being given, to describe the triangle.*

The two angles will either be both adjacent to the given side, or the one adjacent, and the other opposite : in the latter case, find the third angle (Prob. VII.); and the two adjacent angles will thus be known : draw the straight line  $DE$  equal to the given side : at the point  $D$ , make an angle  $EDF$  equal to one of the adjacent angles, and at  $E$ , an angle  $DEG$  equal to the other ; the two lines  $DF$ ,  $EG$ , will cut each other in  $H$  ; and  $DEH$  will be the triangle required (Book I. Prop. VI.).

## PROBLEM X.

*The three sides of a triangle being given, to describe the triangle.*

Let  $A$ ,  $B$ , and  $C$ , be the sides.

Draw  $DE$  equal to the side  $A$  ; from the point  $E$  as a centre, with a radius equal to the second side  $B$ , describe an arc ; from  $D$  as a centre, with a radius equal to the third side  $C$ , describe another arc intersecting the former in  $F$  ; draw  $DF$ ,  $EF$  ; and  $DEF$  will be the triangle required (Book I. Prop. X.).

*Scholium.* If one of the sides were greater than the sum of the other two, the arcs would not intersect each other : but the solution will always be possible, when the sum of two sides, any how taken, is greater than the third.

## PROBLEM XI.

*Two sides of a triangle, and the angle opposite one of them, being given, to describe the triangle.*

Let  $A$  and  $B$  be the given sides, and  $C$  the given angle. There are two cases.

*First.* When the angle  $C$  is a right angle, or when it is obtuse, make the angle  $EDF = C$ ; take  $DE = A$ ; from the point  $E$  as a centre, with a radius equal to the given side  $B$ , describe an arc cutting  $DF$  in  $F$ ; draw  $EF$ : then  $DEF$  will be the triangle required.

In this first case, the side  $B$  must be greater than  $A$ ; for the angle  $C$ , being a right angle, or an obtuse angle, is the greatest angle of the triangle, and the side opposite to it must, therefore, also be the greatest (Book I. Prop. XIII.).

*Secondly.* If the angle  $C$  is acute, and  $B$  greater than  $A$ , the same construction will again apply, and  $DEF$  will be the triangle required.

But if the angle  $C$  is acute, and the side  $B$  less than  $A$ , then the arc described from the centre  $E$ , with the radius  $EF = B$ , will cut the side  $DF$  in two points  $F$  and  $G$ , lying on the same side of  $D$ : hence there will be two triangles  $DEF$ ,  $DEG$ , either of which will satisfy the conditions of the problem.

*Scholium.* If the arc described with  $E$  as a centre, should be tangent to the line  $DG$ , the triangle would be right angled, and there would be but one solution. The problem would be impossible in all cases, if the side  $B$  were less than the perpendicular let fall from  $E$  on the line  $DF$ .

PROBLEM XII.

*The adjacent sides of a parallelogram, with the angle which they contain, being given, to describe the parallelogram*

Let  $A$  and  $B$  be the given sides, and  $C$  the given angle.

Draw the line  $DE = A$ ; at the point  $D$ , make the angle  $EDF = C$ ; take  $DF = B$ ; describe two arcs, the one from  $F$  as a centre, with a radius  $FG = DE$ , the other from  $E$  as a centre, with a radius  $EG = DF$ ; to the point  $G$ , where these arcs intersect each other, draw  $FG$ ,  $EG$ ;

$DEGF$  will be the parallelogram required.

For, the opposite sides are equal, by construction; hence the figure is a parallelogram (Book I. Prop. XXIX.): and it is formed with the given sides and the given angle.

*Cor.* If the given angle is a right angle, the figure will be a rectangle; if, in addition to this, the sides are equal, it will be a square.

PROBLEM XIII.

*To find the centre of a given circle or arc.*

Take three points,  $A$ ,  $B$ ,  $C$ , any where in the circumference, or the arc; draw  $AB$ ,  $BC$ , or suppose them to be drawn; bisect those two lines by the perpendiculars  $DE$ ,  $FG$ : the point  $O$ , where these perpendiculars meet, will be the centre sought (Prop. VI. Sch.).

*Scholium.* The same construction serves for making a circumference pass through three given points  $A$ ,  $B$ ,  $C$ ; and also for describing a circumference, in which, a given triangle  $ABC$  shall be inscribed.

## PROBLEM XIV.

*Through a given point, to draw a tangent to a given circle.*

If the given point  $A$  lies in the circumference, draw the radius  $CA$ , and erect  $AD$  perpendicular to it:  $AD$  will be the tangent required (Prop. IX.).

If the point  $A$  lies without the circle, join  $A$  and the centre, by the straight line  $CA$ : bisect  $CA$  in  $O$ ; from  $O$  as a centre, with the radius  $OC$ , describe a circumference intersecting the given circumference in  $B$ ; draw  $AB$ : this will be the tangent required.

For, drawing  $CB$ , the angle  $CBA$  being inscribed in a semicircle is a right angle (Prop. XVIII. Cor. 2.); therefore  $AB$  is a perpendicular at the extremity of the radius  $CB$ ; therefore it is a tangent.

*Scholium.* When the point  $A$  lies without the circle, there will evidently be always two equal tangents  $AB$ ,  $AD$ , passing through the point  $A$ : they are equal, because the right angled triangles  $CBA$ ,  $CDA$ , have the hypotenuse  $CA$  common, and the side  $CB = CD$ ; hence they are equal (Book I. Prop. XVII.); hence  $AD$  is equal to  $AB$ , and also the angle  $CAD$  to  $CAB$ . And as there can be but one line bisecting the angle  $BAC$ , it follows, that the line which bisects the angle formed by two tangents, must pass through the centre of the circle.

## PROBLEM XV.

*To inscribe a circle in a given triangle.*

Let  $ABC$  be the given triangle.

Bisect the angles  $A$  and  $B$ , by the lines  $AO$  and  $BO$ , meeting in the point  $O$ ; from the point  $O$ , let fall the perpendiculars  $OD$ ,  $OE$ ,  $OF$ , on the three sides of the triangle: these perpendiculars will all be equal. For, by construc-

tion, we have the angle  $DAO = OAF$ , the right angle  $ADO = AFO$ ; hence the third angle  $AOD$  is equal to the third  $AOF$  (Book I. Prop. XXV. Cor. 2.). Moreover, the side  $AO$  is common to the two triangles  $AOD$ ,  $AOF$ ; and the angles adjacent to the equal side are equal: hence the triangles themselves are equal (Book I. Prop. VI.); and  $DO$  is equal to  $OF$ . In the same manner it may be shown that the two triangles  $BOD$ ,  $BOE$ , are equal; therefore  $OD$  is equal to  $OE$ ; therefore the three perpendiculars  $OD$ ,  $OE$ ,  $OF$ , are all equal.

Now, if from the point  $O$  as a centre, with the radius  $OD$ , a circle be described, this circle will evidently be inscribed in the triangle  $ABC$ ; for the side  $AB$ , being perpendicular to the radius at its extremity, is a tangent; and the same thing is true of the sides  $BC$ ,  $AC$ .

*Scholium.* The three lines which bisect the angles of a triangle meet in the same point.

## PROBLEM XVI.

*On a given straight line to describe a segment that shall contain a given angle; that is to say, a segment such, that all the angles inscribed in it, shall be equal to the given angle.*

Let  $AB$  be the given straight line, and  $C$  the given angle.

Produce  $AB$  towards  $D$ ; at the point  $B$ , make the angle  $DBE = C$ ; draw  $BO$  perpendicular to  $BE$ , and  $GO$  perpendicular to  $AB$ , through the middle point  $G$ ; and from the point  $O$ , where these perpendiculars meet, as a centre, with a distance  $OB$ , describe a circle: the required segment will be  $AMB$ .

For, since  $BF$  is a perpendicular at the extremity of the radius  $OB$ , it is a tangent, and the angle  $ABF$  is measured by half the arc  $AKB$  (Prop. XXI.). Also, the angle  $AMB$ , being an inscribed angle, is measured by half the arc  $AKB$ : hence we have  $AMB = ABF = EBD = C$ : hence all the angles inscribed in the segment  $AMB$  are equal to the given angle  $C$ .

*Scholium.* If the given angle were a right angle, the required segment would be a semicircle, described on AB as a diameter.

## PROBLEM XVII.

*To find the numerical ratio of two given straight lines, these lines being supposed to have a common measure.*

Let AB and CD be the given lines.

From the greater AB cut off a part equal to the less CD, as many times as possible; for example, twice, with the remainder BE.

From the line CD, cut off a part equal to the remainder BE, as many times as possible; once, for example, with the remainder DF.

From the first remainder BE, cut off a part equal to the second DF, as many times as possible; once, for example, with the remainder BG.

From the second remainder DF, cut off a part equal to BG the third, as many times as possible.

Continue this process, till a remainder occurs, which is contained exactly a certain number of times in the preceding one.

Then this last remainder will be the common measure of the proposed lines; and regarding it as unity, we shall easily find the values of the preceding remainders; and at last, those of the two proposed lines, and hence their ratio in numbers.

Suppose, for instance, we find GB to be contained exactly twice in FD; BG will be the common measure of the two proposed lines. Put  $BG=1$ ; we shall have  $FD=2$ : but EB contains FD once, *plus* GB; therefore we have  $EB=3$ : CD contains EB once, *plus* FD; therefore we have  $CD=5$ : and, lastly, AB contains CD twice, *plus* EB; therefore we have  $AB=13$ ; hence the ratio of the lines is that of 13 to 5. If the line CD were taken for unity, the line AB would be  $\frac{13}{5}$ ; if AB were taken for unity, CD would be  $\frac{5}{13}$ .

*Scholium.* The method just explained is the same as that employed in arithmetic to find the common divisor of two numbers: it has no need, therefore, of any other demonstration.

How far soever the operation be continued, it is possible that no remainder may ever be found, which shall be contained an exact number of times in the preceding one. When this happens, the two lines have no common measure, and are said to be *incommensurable*. An instance of this will be seen after-

wards, in the ratio of the diagonal to the side of the square. In those cases, therefore, the exact ratio in numbers cannot be found; but, by neglecting the last remainder, an approximate ratio will be obtained, more or less correct, according as the operation has been continued a greater or less number of times.

## PROBLEM XVIII.

*Two angles being given, to find their common measure, if they have one, and by means of it, their ratio in numbers.*

Let A and B be the given angles.

With equal radii describe the arcs CD, EF, to serve as measures for the angles: proceed afterwards in the comparison of the arcs CD, EF, as in the last

problem, since an arc may be cut off from an arc of the same radius, as a straight line from a straight line. We shall thus arrive at the common measure of the arcs CD, EF, if they have one, and thereby at their ratio in numbers. This ratio will be the same as that of the given angles (Prop. XVII.); and if DO is the common measure of the arcs, DAO will be that of the angles.

*Scholium.* According to this method, the absolute value of an angle may be found by comparing the arc which measures it to the whole circumference. If the arc CD, for example, is to the circumference, as 3 is to 25, the angle A will be  $\frac{3}{25}$  of four right angles, or  $\frac{12}{25}$  of one right angle.

It may also happen, that the arcs compared have no common measure; in which case, the numerical ratios of the angles will only be found approximatively with more or less correctness, according as the operation has been continued a greater or less number of times.

## BOOK IV.

OF THE PROPORTIONS OF FIGURES, AND THE MEASUREMENT  
OF AREAS.*Definitions.*

1. Similar figures are those which have the angles of the one equal to the angles of the other, each to each, and the sides about the equal angles proportional.

2. Any two sides, or any two angles, which have like positions in two similar figures, are called *homologous* sides or angles.

3. In two different circles, *similar arcs, sectors, or segments*, are those which correspond to equal angles at the centre.

Thus, if the angles  $A$  and  $O$  are equal, the arc  $BC$  will be similar to  $DE$ , the sector  $BAC$  to the sector  $DOE$ , and the segment whose chord is  $BC$ , to the segment whose chord is  $DE$ .

4. The *base* of any rectilineal figure, is the side on which the figure is supposed to stand.

5. The *altitude* of a triangle is the perpendicular let fall from the vertex of an angle on the opposite side, taken as a base. Thus,  $AD$  is the altitude of the triangle  $BAC$ .

6. The *altitude* of a parallelogram is the perpendicular which measures the distance between two opposite sides taken as bases. Thus,  $EF$  is the altitude of the parallelogram  $DB$ .

7. The altitude of a trapezoid is the perpendicular drawn between its two parallel sides. Thus,  $EF$  is the altitude of the trapezoid  $DB$ .

8. The *area* and *surface* of a figure, are terms very nearly synonymous. The *area* designates more particularly the superficial content of the figure. The area is expressed numeri-

cally by the number of times which the figure contains some other area, that is assumed for its measuring unit.

9. Figures have *equal* areas, when they contain the same measuring unit an equal number of times.

10. Figures which have equal areas are called *equivalent*. The term *equal*, when applied to figures, designates those which are equal in every respect, and which being applied to each other will coincide in all their parts (Ax. 13.): the term *equivalent* implies an equality in one respect only: namely, an equality between the measures of figures.

We may here premise, that several of the demonstrations are grounded on some of the simpler operations of algebra, which are themselves dependent on admitted axioms. Thus, if we have  $A=B+C$ , and if each member is multiplied by the same quantity  $M$ , we may infer that  $A \times M = B \times M + C \times M$ ; in like manner, if we have,  $A=B+C$ , and  $D=E-C$ , and if the equal quantities are added together, then expunging the  $+C$  and  $-C$ , which destroy each other, we infer that  $A+D=B+E$ , and so of others. All this is evident enough of itself; but in cases of difficulty, it will be useful to consult some algebraical treatise, and thus to combine the study of the two sciences.

PROPOSITION I. THEOREM.

*Parallelograms which have equal bases and equal altitudes, are equivalent.*

Let  $AB$  be the common base of the two parallelograms  $ABCD$ ,  $ABEF$ : and since they are supposed to have the same altitude, their upper bases  $DC$ ,  $FE$ , will be both situated in one straight line parallel to  $AB$ .

Now, from the nature of parallelograms, we have  $AD=BC$ , and  $AF=BE$ ; for the same reason, we have  $DC=AB$ , and  $FE=AB$ ; hence  $DC=FE$ : hence, if  $DC$  and  $FE$  be taken away from the same line  $DE$ , the remainders  $CE$  and  $DF$  will be equal: hence it follows that the triangles  $DAF$ ,  $CBE$ , are mutually equilateral, and consequently equal (Book I. Prop. X.).

But if from the quadrilateral  $ABED$ , we take away the triangle  $ADF$ , there will remain the parallelogram  $ABEF$ ; and if from the same quadrilateral  $ABED$ , we take away the equal triangle  $CBE$ , there will remain the parallelogram  $ABCD$

Hence these two parallelograms  $ABCD$ ,  $ABEF$ , which have the same base and altitude, are equivalent.

*Cor.* Every parallelogram is equivalent to the rectangle which has the same base and the same altitude.

### PROPOSITION II. THEOREM.

*Every triangle is half the parallelogram which has the same base and the same altitude.*

Let  $ABCD$  be a parallelogram, and  $ABE$  a triangle, having the same base  $AB$ , and the same altitude: then will the triangle be half the parallelogram.

For, since the triangle and the parallelogram have the same altitude, the vertex  $E$  of the triangle, will be in the line  $EC$ , parallel to the base  $AB$ . Produce  $BA$ , and from  $E$  draw  $EF$  parallel to  $AD$ . The triangle  $FBE$  is half the parallelogram  $FC$ , and the triangle  $FAE$  half the parallelogram  $FD$  (Book I. Prop. XXVIII. Cor.).

Now, if from the parallelogram  $FC$ , there be taken the parallelogram  $FD$ , there will remain the parallelogram  $AC$ : and if from the triangle  $FBE$ , which is half the first parallelogram, there be taken the triangle  $FAE$ , half the second, there will remain the triangle  $ABE$ , equal to half the parallelogram  $AC$ .

*Cor. 1.* Hence a triangle  $ABE$  is half of the rectangle  $ABGH$ , which has the same base  $AB$ , and the same altitude  $AH$ : for the rectangle  $ABGH$  is equivalent to the parallelogram  $ABCD$  (Prop. I. Cor.).

*Cor. 2.* All triangles, which have equal bases and altitudes, are equivalent, being halves of equivalent parallelograms.

### PROPOSITION III. THEOREM.

*Two rectangles having the same altitude, are to each other as their bases.*

Let  $ABCD$ ,  $AEFD$ , be two rectangles having the common altitude  $AD$ : they are to each other as their bases  $AB$ ,  $AE$ .

Suppose, first, that the bases are commensurable, and are to each other, for example, as the numbers 7 and 4. If  $AB$  be divided into 7 equal parts,  $AE$  will contain 4 of those parts: at each point of division erect a perpendicular to the base; seven partial rectangles will thus be formed, all equal to each other, because all have the same base and altitude. The rectangle  $ABCD$  will contain seven partial rectangles, while  $AEFD$  will contain four: hence the rectangle  $ABCD$  is to  $AEFD$  as 7 is to 4, or as  $AB$  is to  $AE$ . The same reasoning may be applied to any other ratio equally with that of 7 to 4: hence, whatever be that ratio, if its terms be commensurable, we shall have

$$ABCD : AEFD :: AB : AE.$$

Suppose, in the second place, that the bases  $AB$ ,  $AE$ , are incommensurable: it is to be shown that we shall still have

$$ABCD : AEFD :: AB : AE.$$

For if not, the first three terms continuing the same, the fourth must be greater or less than  $AE$ . Suppose it to be greater, and that we have

$$ABCD : AEFD :: AB : AO.$$

Divide the line  $AB$  into equal parts, each less than  $EO$ . There will be at least one point  $I$  of division between  $E$  and  $O$ : from this point draw  $IK$  perpendicular to  $AI$ : the bases  $AB$ ,  $AI$ , will be commensurable, and thus, from what is proved above, we shall have

$$ABCD : AIKD :: AB : AI.$$

But by the hypothesis we have

$$ABCD : AEFD :: AB : AO.$$

In these two proportions the antecedents are equal; hence the consequents are proportional (Book II. Prop. IV.); and we find

$$AIKD : AEFD :: AI : AO.$$

But  $AO$  is greater than  $AI$ ; hence, if this proportion is correct, the rectangle  $AEFD$  must be greater than  $AIKD$ : on the contrary, however, it is less; hence the proportion is impossible; therefore  $ABCD$  cannot be to  $AEFD$ , as  $AB$  is to a line greater than  $AE$

Exactly in the same manner, it may be shown that the fourth term of the proportion cannot be less than AE ; therefore it is equal to AE.

Hence, whatever be the ratio of the bases, two rectangles ABCD, AEFD, of the same altitude, are to each other as their bases AB, AE.

#### PROPOSITION IV. THEOREM.

*Any two rectangles are to each other as the products of their bases multiplied by their altitudes.*

Let ABCD, AEGF, be two rectangles ; then will the rectangle,

$$ABCD : AEGF :: AB.AD : AF.AE.$$

Having placed the two rectangles, so that the angles at A are vertical, produce the sides GE, CD, till they meet in H. The two rectangles ABCD, AEHD, having the same altitude AD, are to each other as their bases AB, AE : in like manner the two rectangles AEHD, AEGF, having the same altitude AE, are to each other as their bases AD, AF : thus we have the two proportions,

$$ABCD : AEHD :: AB : AE,$$

$$AEHD : AEGF :: AD : AF.$$

Multiplying the corresponding terms of these proportions together, and observing that the term AEHD may be omitted, since it is a multiplier of both the antecedent and the consequent, we shall have

$$ABCD : AEGF :: AB \times AD : AE \times AF.$$

*Scholium.* Hence the product of the base by the altitude may be assumed as the measure of a rectangle, provided we understand by this product, the product of two numbers, one of which is the number of linear units contained in the base, the other the number of linear units contained in the altitude. This product will give the number of superficial units in the surface ; because, for one unit in height, there are as many superficial units as there are linear units in the base ; for two units in height twice as many ; for three units in height, three times as many, &c.

Still this measure is not absolute, but relative : it supposes

that the area of any other rectangle is computed in a similar manner, by measuring its sides with the same linear unit ; a second product is thus obtained, and the ratio of the two products is the same as that of the rectangles, agreeably to the proposition just demonstrated.

For example, if the base of the rectangle A contains three units, and its altitude ten, that rectangle will be represented by the number  $3 \times 10$ , or 30, a number which signifies nothing while thus isolated ; but if there is a second rectangle B, the base of which contains twelve units, and the altitude seven, this second rectangle will be represented by the number  $12 \times 7 = 84$  ; and we shall hence be entitled to conclude that the two rectangles are to each other as 30 is to 84 ; and therefore, if the rectangle A were to be assumed as the unit of measurement in surfaces, the rectangle B would then have  $\frac{84}{30}$  for its absolute measure, in other words, it would be equal to  $\frac{84}{30}$  of a superficial unit.

It is more common and more simple, to assume the square as the unit of surface ; and to select that square, whose side is the unit of length. In this case the measurement which we have

regarded merely as relative, becomes absolute : the number 30, for instance, by which the rectangle A was measured, now represents 30 superficial units, or 30 of those squares, which have each of their sides equal to unity, as the diagram exhibits.

In geometry the product of two lines frequently means the same thing as their *rectangle*, and this expression has passed into arithmetic, where it serves to designate the product of two unequal numbers, the expression *square* being employed to designate the product of a number multiplied by itself.

The arithmetical squares of 1, 2, 3, &c. are 1, 4, 9, &c. So likewise, the geometrical square constructed on a double line is evidently four times greater than the square on a single one ; on a triple line it is nine times greater, &c.

## PROPOSITION V. THEOREM.

*The area of any parallelogram is equal to the product of its base by its altitude.*

For, the parallelogram ABCD is equivalent to the rectangle ABEF, which has the same base AB, and the same altitude BE (Prop. I. Cor.): but this rectangle is measured by  $AB \times BE$  (Prop. IV. Sch.); therefore,  $AB \times BE$  is equal to the area of the parallelogram ABCD.

*Cor.* Parallelograms of the same base are to each other as their altitudes; and parallelograms of the same altitude are to each other as their bases: for, let B be the common base, and C and D the altitudes of two parallelograms:

then,  $B \times C : B \times D :: C : D$ , (Book II. Prop. VII.)

And if A and B be the bases, and C the common altitude, we shall have

$$A \times C : B \times C :: A : B.$$

And parallelograms, generally, are to each other as the products of their bases and altitudes.

## PROPOSITION VI. THEOREM.

*The area of a triangle is equal to the product of its base by half its altitude.*

For, the triangle ABC is half of the parallelogram ABCE, which has the same base BC, and the same altitude AD (Prop. II.); but the area of the parallelogram is equal to  $BC \times AD$  (Prop. V.); hence that of the triangle must be  $\frac{1}{2}BC \times AD$ , or  $BC \times \frac{1}{2}AD$ .

*Cor.* Two triangles of the same altitude are to each other as their bases, and two triangles of the same base are to each other as their altitudes. And triangles generally, are to each other, as the products of their bases and altitudes.

## PROPOSITION VII. THEOREM.

*The area of a trapezoid is equal to its altitude multiplied by the half sum of its parallel bases.*

Let ABCD be a trapezoid, EF its altitude, AB and CD its parallel bases; then will its area be equal to  $EF \times \frac{1}{2}(AB + CD)$ .

Through I, the middle point of the side BC, draw KL parallel to the opposite side AD; and produce DC till it meets KL.

In the triangles IBL, ICK, we have the side IB=IC, by construction; the angle LIB=CIK; and since CK and BL are parallel, the angle IBL=ICK (Book I. Prop. XX. Cor. 2.); hence the triangles are equal (Book I. Prop. VI.); therefore, the trapezoid ABCD is equivalent to the parallelogram ADKL, and is measured by  $EF \times AL$ .

But we have  $AL=DK$ ; and since the triangles IBL and KCI are equal, the side  $BL=CK$ : hence,  $AB+CD=AL+DK=2AL$ ; hence AL is the half sum of the bases AB, CD; hence the area of the trapezoid ABCD, is equal to the altitude EF multiplied by the half sum of the bases AB, CD, a result which is expressed thus:  $ABCD = EF \times \frac{AB+CD}{2}$ .

*Scholium.* If through I, the middle point of BC, the line IH be drawn parallel to the base AB, the point H will also be the middle of AD. For, since the figure AHIL is a parallelogram, as also DHIK, their opposite sides being parallel, we have  $AH=IL$ , and  $DH=IK$ ; but since the triangles BIL, CIK, are equal, we already have  $IL=IK$ ; therefore,  $AH=DH$ .

It may be observed, that the line  $HI=AL$  is equal to  $\frac{AB+CD}{2}$ ; hence the area of the trapezoid may also be expressed by  $EF \times HI$ : it is therefore equal to the altitude of the trapezoid multiplied by the line which connects the middle points of its inclined sides.

## PROPOSITION VIII. THEOREM.

*If a line is divided into two parts, the square described on the whole line is equivalent to the sum of the squares described on the parts, together with twice the rectangle contained by the parts.*

Let AC be the line, and B the point of division ; then, is

$$AC^2 \text{ or } (AB + BC)^2 = AB^2 + BC^2 + 2AB \times BC.$$

Construct the square ACDE ; take AF = AB ; draw FG parallel to AC, and BH parallel to AE.

The square ACDE is made up of four parts ; the first ABIF is the square described on AB, since we made AF = AB : the second IDGH is the square described on IG, or BC ; for since we have AC = AE and AB = AF, the difference, AC — AB must be equal to the difference AE — AF, which gives BC = EF ; but IG is equal to BC, and DG to EF, since the lines are parallel ; therefore IGDH is equal to a square described on BC. And those two squares being taken away from the whole square, there remains the two rectangles BCGI, EFIH, each of which is measured by AB × BC : hence the large square is equivalent to the two small squares, together with the two rectangles.

*Cor.* If the line AC were divided into two equal parts, the two rectangles EI, IC, would become squares, and the square described on the whole line would be equivalent to four times the square described on half the line.

*Scholium.* This property is equivalent to the property demonstrated in algebra, in obtaining the square of a binomial ; which is expressed thus :

$$(a + b)^2 = a^2 + 2ab + b^2.$$

## PROPOSITION IX. THEOREM.

*The square described on the difference of two lines, is equivalent to the sum of the squares described on the lines, minus twice the rectangle contained by the lines.*

Let  $AB$  and  $BC$  be two lines,  $AC$  their difference; then is  $AC^2$ , or  $(AB-BC)^2=AB^2+BC^2-2AB \times BC$ .

Describe the square  $ABIF$ ; take  $AE=AC$ ; draw  $CG$  parallel to  $BI$ ,  $HK$  parallel to  $AB$ , and complete the square  $EFLK$ .

The two rectangles  $CBIG$ ,  $GLKD$ , are each measured by  $AB \times BC$ ; take them away from the whole figure  $ABILKEA$ , which is equivalent to  $AB^2+BC^2$ , and there will evidently remain the square  $ACDE$ ; hence the theorem is true.

*Scholium.* This proposition is equivalent to the algebraical formula,  $(a-b)^2=a^2-2ab+b^2$ .

PROPOSITION X. THEOREM.

*The rectangle contained by the sum and the difference of two lines, is equivalent to the difference of the squares of those lines.*

Let  $AB$ ,  $BC$ , be two lines; then, will

$$(AB+BC) \times (AB-BC) = AB^2 - BC^2.$$

On  $AB$  and  $AC$ , describe the squares  $ABIF$ ,  $ACDE$ ; produce  $AB$  till the produced part  $BK$  is equal to  $BC$ ; and complete the rectangle  $AKLE$ .

The base  $AK$  of the rectangle  $EK$ , is the sum of the two lines  $AB$ ,  $BC$ ; its altitude  $AE$  is the difference of the same lines; therefore the rectangle  $AKLE$  is equal to  $(AB+BC) \times (AB-BC)$ . But this rectangle is composed of the two parts  $ABHE + BHLK$ ; and the part  $BHLK$  is equal to the rectangle  $EDGF$ , because  $BH$  is equal to  $DE$ , and  $BK$  to  $EF$ ; hence  $AKLE$  is equal to  $ABHE + EDGF$ . These two parts make up the square  $ABIF$  minus the square  $DHIG$ , which latter is equal to a square described on  $BC$ : hence we have

$$(AB+BC) \times (AB-BC) = AB^2 - BC^2.$$

*Scholium.* This proposition is equivalent to the algebraical formula,  $(a+b) \times (a-b) = a^2 - b^2$ .

## PROPOSITION XI. THEOREM.

*The square described on the hypotenuse of a right angled triangle is equivalent to the sum of the squares described on the other two sides.*

Let the triangle  $ABC$  be right angled at  $A$ . Having described squares on the three sides, let fall from  $A$ , on the hypotenuse, the perpendicular  $AD$ , which produce to  $E$ ; and draw the diagonals  $AF$ ,  $CH$ .

The angle  $ABF$  is made up of the angle  $ABC$ , together with the right angle  $CBF$ ; the angle  $CBH$  is made up of the same angle  $ABC$ , together with the right angle  $ABH$ ; hence the angle  $ABF$  is equal to  $HBC$ . But we have  $AB=BH$ , being sides of the same square; and  $BF=BC$ , for the same reason: therefore the triangles  $ABF$ ,  $HBC$ , have two sides and the included angle in each equal; therefore they are themselves equal (Book I. Prop. V.).

The triangle  $ABF$  is half of the rectangle  $BE$ , because they have the same base  $BF$ , and the same altitude  $BD$  (Prop. II. Cor. 1.). The triangle  $HBC$  is in like manner half of the square  $AH$ : for the angles  $BAC$ ,  $BAL$ , being both right angles,  $AC$  and  $AL$  form one and the same straight line parallel to  $HB$  (Book I. Prop. III.); and consequently the triangle  $HBC$ , and the square  $AH$ , which have the common base  $BH$ , have also the common altitude  $AB$ ; hence the triangle is half of the square.

The triangle  $ABF$  has already been proved equal to the triangle  $HBC$ ; hence the rectangle  $BDEF$ , which is double of the triangle  $ABF$ , must be equivalent to the square  $AH$ , which is double of the triangle  $HBC$ . In the same manner it may be proved, that the rectangle  $CDEG$  is equivalent to the square  $AI$ . But the two rectangles  $BDEF$ ,  $CDEG$ , taken together, make up the square  $BCGF$ : therefore the square  $BCGF$ , described on the hypotenuse, is equivalent to the sum of the squares  $ABHL$ ,  $ACIK$ , described on the two other sides; in other words,  $BC^2 = AB^2 + AC^2$ .

*Cor. 1.* Hence the square of one of the sides of a right angled triangle is equivalent to the square of the hypotenuse diminished by the square of the other side; which is thus expressed:  $AB^2 = BC^2 - AC^2$ .

*Cor. 2.* It has just been shown that the square  $AH$  is equivalent to the rectangle  $BDEF$ ; but by reason of the common altitude  $BF$ , the square  $BCGF$  is to the rectangle  $BDEF$  as the base  $BC$  is to the base  $BD$ ; therefore we have

$$BC^2 : AB^2 :: BC : BD.$$

Hence the square of the hypotenuse is to the square of one of the sides about the right angle, as the hypotenuse is to the segment adjacent to that side. The word *segment* here denotes that part of the hypotenuse, which is cut off by the perpendicular let fall from the right angle: thus  $BD$  is the segment adjacent to the side  $AB$ ; and  $DC$  is the segment adjacent to the side  $AC$ . We might have, in like manner,

$$BC^2 : AC^2 :: BC : CD.$$

*Cor. 3.* The rectangles  $BDEF$ ,  $DCGE$ , having likewise the same altitude, are to each other as their bases  $BD$ ,  $CD$ . But these rectangles are equivalent to the squares  $AH$ ,  $AI$ ; therefore we have  $AB^2 : AC^2 :: BD : DC$ .

Hence the squares of the two sides containing the right angle, are to each other as the segments of the hypotenuse which lie adjacent to those sides.

*Cor. 4.* Let  $ABCD$  be a square, and  $AC$  its diagonal: the triangle  $ABC$  being right angled and isosceles, we shall have  $AC^2 = AB^2 + BC^2 = 2AB^2$ : hence the square described on the diagonal  $AC$ , is double of the square described on the side  $AB$ .

This property may be exhibited more plainly, by drawing parallels to  $BD$ , through the points  $A$  and  $C$ , and parallels to  $AC$ , through the points  $B$  and  $D$ . A new square  $EFGH$  will thus be formed, equal to the square of  $AC$ . Now  $EFGH$  evidently contains eight triangles each equal to  $ABE$ ; and  $ABCD$  contains four such triangles: hence  $EFGH$  is double of  $ABCD$ .

Since we have  $AC^2 : AB^2 :: 2 : 1$ ; by extracting the square roots, we shall have  $AC : AB :: \sqrt{2} : 1$ ; hence, the diagonal of a square is incommensurable with its side; a property which will be explained more fully in another place.

## PROPOSITION XII. THEOREM.

*In every triangle, the square of a side opposite an acute angle is less than the sum of the squares of the other two sides, by twice the rectangle contained by the base and the distance from the acute angle to the foot of the perpendicular let fall from the opposite angle on the base, or on the base produced.*

Let  $ABC$  be a triangle, and  $AD$  perpendicular to the base  $CB$ ; then will  $AB^2 = AC^2 + BC^2 - 2BC \times CD$ .

There are two cases.

*First.* When the perpendicular falls within the triangle  $ABC$ , we have  $BD = BC - CD$ , and consequently  $BD^2 = BC^2 + CD^2 - 2BC \times CD$  (Prop. IX.). Adding  $AD^2$  to each, and observing that the right angled triangles  $ABD$ ,  $ADC$ , give  $AD^2 + BD^2 = AB^2$ , and  $AD^2 + CD^2 = AC^2$ , we have  $AB^2 = BC^2 + AC^2 - 2BC \times CD$ .

*Secondly.* When the perpendicular  $AD$  falls without the triangle  $ABC$ , we have  $BD = CD - BC$ ; and consequently  $BD^2 = CD^2 + BC^2 - 2CD \times BC$  (Prop. IX.). Adding  $AD^2$  to both, we find, as before,  $AB^2 = BC^2 + AC^2 - 2BC \times CD$ .

## PROPOSITION XIII. THEOREM.

*In every obtuse angled triangle, the square of the side opposite the obtuse angle is greater than the sum of the squares of the other two sides by twice the rectangle contained by the base and the distance from the obtuse angle to the foot of the perpendicular let fall from the opposite angle on the base produced.*

Let  $ACB$  be a triangle,  $C$  the obtuse angle, and  $AD$  perpendicular to  $BC$  produced; then will  $AB^2 = AC^2 + BC^2 + 2BC \times CD$ .

The perpendicular cannot fall within the triangle; for, if it fell at any point such as  $E$ , there would be in the triangle  $ACE$ , the right angle  $E$ , and the obtuse angle  $C$ , which is impossible (Book I. Prop. XXV. Cor. 3.):

hence the perpendicular falls without ; and we have  $BD = BC + CD$ . From this there results  $BD^2 = BC^2 + CD^2 + 2BC \times CD$  (Prop. VIII.). Adding  $AD^2$  to both, and reducing the sums as in the last theorem, we find  $AB^2 = BC^2 + AC^2 + 2BC \times CD$ .

*Scholium.* The right angled triangle is the only one in which the squares described on the two sides are together equivalent to the square described on the third ; for if the angle contained by the two sides is acute, the sum of their squares will be greater than the square of the opposite side ; if obtuse, it will be less.

PROPOSITION XIV. THEOREM.

*In any triangle, if a straight line be drawn from the vertex to the middle of the base, twice the square of this line, together with twice the square of half the base, is equivalent to the sum of the squares of the other two sides of the triangle.*

Let  $ABC$  be any triangle, and  $AE$  a line drawn to the middle of the base  $BC$  ; then will

$$2AE^2 + 2BE^2 = AB^2 + AC^2.$$

On  $BC$ , let fall the perpendicular  $AD$ .

Then, by Prop. XII.

$$AC^2 = AE^2 + EC^2 - 2EC \times ED.$$

And by Prop. XIII.

$$AB^2 = AE^2 + EB^2 + 2EB \times ED.$$

Hence, by adding, and observing that  $EB$  and  $EC$  are equal, we have

$$AB^2 + AC^2 = 2AE^2 + 2EB^2.$$

*Cor.* Hence, in every parallelogram the squares of the sides are together equivalent to the squares of the diagonals.

For the diagonals  $AC$ ,  $BD$ , bisect each other (Book I. Prop. XXXI.) ; consequently the triangle  $ABC$  gives

$$AB^2 + BC^2 = 2AE^2 + 2BE^2.$$

The triangle  $ADC$  gives, in like manner.

$$AD^2 + DC^2 = 2AE^2 + 2DE^2.$$

Adding the corresponding members together, and observing that  $BE$  and  $DE$  are equal, we shall have

$$AB^2 + AD^2 + DC^2 + BC^2 = 4AE^2 + 4DE^2.$$

But  $4AE^2$  is the square of  $2AE$ , or of  $AC$  ;  $4DE^2$  is the square of  $BD$  (Prop. VIII. Cor.) : hence the squares of the sides are together equivalent to the squares of the diagonals.

## PROPOSITION XV. THEOREM.

*If a line be drawn parallel to the base of a triangle, it will divide the other sides proportionally.*

Let  $ABC$  be a triangle, and  $DE$  a straight line drawn parallel to the base  $BC$ ; then will

$$AD : DB :: AE : EC.$$

Draw  $BE$  and  $DC$ . The two triangles  $BDE$ ,  $DEC$  having the same base  $DE$ , and the same altitude, since both their vertices lie in a line parallel to the base, are equivalent (Prop. II. Cor. 2.).

The triangles  $ADE$ ,  $BDE$ , whose common vertex is  $E$ , have the same altitude, and are to each other as their bases (Prop. VI. Cor.); hence we have

$$ADE : BDE :: AD : DB.$$

The triangles  $ADE$ ,  $DEC$ , whose common vertex is  $D$ , have also the same altitude, and are to each other as their bases; hence

$$ADE : DEC :: AE : EC.$$

But the triangles  $BDE$ ,  $DEC$ , are equivalent; and therefore, we have (Book II. Prop. IV. Cor.)

$$AD : DB :: AE : EC.$$

*Cor. 1.* Hence, by composition, we have  $AD + DB : AD :: AE + EC : AE$ , or  $AB : AD :: AC : AE$ ; and also  $AB : BD :: AC : CE$ .

*Cor. 2.* If between two straight lines  $AB$ ,  $CD$ , any number of parallels  $AC$ ,  $EF$ ,  $GH$ ,  $BD$ , &c. be drawn, those straight lines are cut proportionally, and we shall have  $AE : CF :: EG : FH :: GB : HD$ .

For, let  $O$  be the point where  $AB$  and  $CD$  meet. In the triangle  $OEF$ , the line  $AC$  being drawn parallel to the base  $EF$ , we shall have  $OE : AE :: OF : CF$ , or  $OE : OF :: AE : CF$ . In the triangle  $OGH$ , we shall likewise have  $OE : EG :: OF : FH$ , or  $OE : OF :: EG : FH$ . And by reason of the common ratio  $OE : OF$ , those two proportions give  $AE : CF :: EG : FH$ . It may be proved in the same manner, that  $EG : FH :: GB : HD$ , and so on; hence the lines  $AB$ ,  $CD$ , are cut proportionally by the parallels  $AC$ ,  $EF$ ,  $GH$ , &c.

## PROPOSITION XVI. THEOREM.

*Conversely, if two sides of a triangle are cut proportionally by a straight line, this straight line will be parallel to the third side.*

In the triangle  $ABC$ , let the line  $DE$  be drawn, making  $AD : DB :: AE : EC$ ; then will  $DE$  be parallel to  $BC$ .

For, if  $DE$  is not parallel to  $BC$ , draw  $DO$  parallel to it. Then, by the preceding theorem, we shall have  $AD : DB :: AO : OC$ . But by hypothesis, we have  $AD : DB :: AE : EC$ ; hence we must have  $AO : OC :: AE : EC$ , or  $AO : AE :: OC : EC$ ; an impossible result, since  $AO$ , the one antecedent, is less than its consequent  $AE$ , and  $OC$ , the other antecedent, is greater than its consequent  $EC$ . Hence the parallel to  $BC$ , drawn from the point  $D$ , cannot differ from  $DE$ ; hence  $DE$  is that parallel.

*Scholium.* The same conclusion would be true, if the proportion  $AB : AD :: AC : AE$  were the proposed one. For this proportion would give  $AB - AD : AD :: AC - AE : AE$ , or  $BD : AD :: CE : AE$ .

## PROPOSITION XVII. THEOREM.

*The line which bisects the vertical angle of a triangle, divides the base into two segments, which are proportional to the adjacent sides.*

In the triangle  $ACB$ , let  $AD$  be drawn, bisecting the angle  $CAB$ ; then will

$$BD : CD :: AB : AC.$$

Through the point  $C$ , draw  $CE$  parallel to  $AD$  till it meets  $BA$  produced.

In the triangle  $BCE$ , the line  $AD$  is parallel to the base  $CE$ ; hence we have the proportion (Prop. XV.),

$$BD : DC :: AB : AE.$$

But the triangle  $ACE$  is isosceles: for, since  $AD$ ,  $CE$  are parallel, we have the angle  $ACE = DAC$ , and the angle  $AEC = BAD$  (Book I. Prop. XX. Cor. 2 & 3.); but, by hypothesis,  $DAC = BAD$ ; hence the angle  $ACE = AEC$ , and consequently  $AE = AC$  (Book I. Prop. XII.). In place of  $AE$  in the above proportion, substitute  $AC$ , and we shall have  $BD : DC :: AB : AC$ .

## PROPOSITION XVIII. THEOREM.

*Two equiangular triangles have their homologous sides proportional, and are similar.*

Let  $ABC, CDE$  be two triangles which have their angles equal each to each, namely,  $BAC = CDE$ ,  $ABC = DCE$  and  $ACB = DEC$ ; then the homologous sides, or the sides adjacent to the equal angles, will be proportional, so that we shall have  $BC : CE :: AB : CD :: AC : DE$ .

Place the homologous sides  $BC, CE$  in the same straight line; and produce the sides  $BA, ED$ , till they meet in  $F$ .

Since  $BCE$  is a straight line, and the angle  $BCA$  is equal to  $CED$ , it follows that  $AC$  is parallel to  $DE$  (Book I. Prop. XIX. Cor. 2.). In like manner, since the angle  $ABC$  is equal to  $DCE$ , the line  $AB$  is parallel to  $DC$ . Hence the figure  $ACDF$  is a parallelogram.

In the triangle  $BFE$ , the line  $AC$  is parallel to the base  $FE$ ; hence we have  $BC : CE :: BA : AF$  (Prop. XV.); or putting  $CD$  in the place of its equal  $AF$ ,

$$BC : CE :: BA : CD.$$

In the same triangle  $BEF$ ,  $CD$  is parallel to  $BF$  which may be considered as the base; and we have the proportion  $BC : CE :: FD : DE$ ; or putting  $AC$  in the place of its equal  $FD$ ,

$$BC : CE :: AC : DE.$$

And finally, since both these proportions contain the same ratio  $BC : CE$ , we have

$$AC : DE :: BA : CD.$$

Thus the equiangular triangles  $BAC, CED$ , have their homologous sides proportional. But two figures are similar when they have their angles equal, each to each, and their homologous sides proportional (Def. 1.); consequently the equiangular triangles  $BAC, CED$ , are two similar figures.

*Cor.* For the similarity of two triangles, it is enough that they have two angles equal, each to each; since then, the third will also be equal in both, and the two triangles will be equiangular.

*Scholium.* Observe, that in similar triangles, the homologous sides are opposite to the equal angles ; thus the angle ACB being equal to DEC, the side AB is homologous to DC ; in like manner, AC and DE are homologous, because opposite to the equal angles ABC, DCE. When the homologous sides are determined, it is easy to form the proportions :

$$AB : DC :: AC : DE :: BC : CE.$$

PROPOSITION XIX. THEOREM.

*Two triangles, which have their homologous sides proportional, are equiangular and similar.*

In the two triangles BAC, DEF, suppose we have  $BC : EF :: AB : DE :: AC : DF$  ; then will the triangles ABC, DEF have their angles equal, namely,  $A=D$ ,  $B=E$ ,  $C=F$ .

At the point E, make the angle  $FEG=B$ , and at F, the angle  $EFG=C$  ; the third G will be equal to the third A, and the two triangles ABC, EFG will be equiangular (Book I. Prop. XXV. Cor. 2.). Therefore, by the last theorem, we shall have  $BC : EF :: AB : EG$  ; but, by hypothesis, we have  $BC : EF :: AB : DE$  ; hence  $EG=DE$ . By the same theorem, we shall also have  $BC : EF :: AC : FG$  ; and by hypothesis, we have  $BC : EF :: AC : DF$  ; hence  $FG=DF$ . Hence the triangles EGF, DEF, having their three sides equal, each to each, are themselves equal (Book I. Prop. X.). But by construction, the triangles EGF and ABC are equiangular : hence DEF and ABC are also equiangular and similar.

*Scholium 1.* By the last two propositions, it appears that in triangles, equality among the angles is a consequence of proportionality among the sides, and conversely ; so that either of those conditions sufficiently determines the similarity of two triangles. The case is different with regard to figures of more than three sides : even in quadrilaterals, the proportion between the sides may be altered without altering the angles, or the angles may be altered without altering the proportion between the sides ; and thus proportionality among the sides cannot be a consequence of equality among the angles of two quadrilaterals, or *vice versa*. It is evident, for example, that

by drawing  $EF$  parallel to  $BC$ , the angles of the quadrilateral  $AEFD$ , are made equal to those of  $ABCD$ , though the proportion between the sides is different; and, in like manner, without changing the four sides  $AB$ ,  $BC$ ,  $CD$ ,  $AD$ , we can make the point  $B$  approach  $D$  or recede from it, which will change the angles.

*Scholium 2.* The two preceding propositions, which in strictness form but one, together with that relating to the square of the hypotenuse, are the most important and fertile in results of any in geometry: they are almost sufficient of themselves for every application to subsequent reasoning, and for solving every problem. The reason is, that all figures may be divided into triangles, and any triangle into two right angled triangles. Thus the general properties of triangles include, by implication, those of all figures.

#### PROPOSITION XX. THEOREM.

*Two triangles, which have an angle of the one equal to an angle of the other, and the sides containing those angles proportional, are similar.*

In the two triangles  $ABC$ ,  $DEF$ , let the angles  $A$  and  $D$  be equal; then, if  $AB : DE :: AC : DF$ , the two triangles will be similar.

Take  $AG = DE$ , and draw  $GH$  parallel to  $BC$ . The angle  $AGH$  will be equal to the angle  $ABC$  (Book I. Prop. XX. Cor 3.); and the triangles  $AGH$ ,  $ABC$ , will be equiangular: hence we shall have  $AB : AG :: AC : AH$ . But by hypothesis, we have  $AB : DE :: AC : DF$ ; and by construction,  $AG = DE$ : hence  $AH = DF$ . The two triangles  $AGH$ ,  $DEF$ , have an equal angle included between equal sides; therefore they are equal; but the triangle  $AGH$  is similar to  $ABC$ : therefore  $DEF$  is also similar to  $ABC$ .

## PROPOSITION XXI. THEOREM.

*Two triangles, which have their homologous sides parallel, or perpendicular to each other, are similar.*

Let  $BAC$ ,  $EDF$ , be two triangles.

*First.* If the side  $AB$  is parallel to  $DE$ , and  $BC$  to  $EF$ , the angle  $ABC$  will be equal to  $DEF$  (Book I. Prop. XXIV.); if  $AC$  is parallel to  $DF$ , the angle  $ACB$  will be equal to  $DFE$ , and also  $BAC$  to  $EDF$ ; hence the triangles  $ABC$ ,  $DEF$ , are equiangular; consequently they are similar (Prop. XVIII.).

*Secondly.* If the side  $DE$  is perpendicular to  $AB$ , and the side  $DF$  to  $AC$ , the two angles  $I$  and  $H$  of the quadrilateral  $AIDH$  will be right angles; and since all the four angles are together equal to four right angles (Book I. Prop. XXVI. Cor. 1.), the remaining two  $IAH$ ,  $IDH$ , will be together equal to two right angles. But the two angles  $EDF$ ,  $IDH$ , are also equal to two right angles: hence the angle  $EDF$  is equal to  $IAH$  or  $BAC$ . In like manner, if the third side  $EF$  is perpendicular to the third side  $BC$ , it may be shown that the angle  $DFE$  is equal to  $C$ , and  $DEF$  to  $B$ : hence the triangles  $ABC$ ,  $DEF$ , which have the sides of the one perpendicular to the corresponding sides of the other, are equiangular and similar.

*Scholium.* In the case of the sides being parallel, the homologous sides are the parallel ones: in the case of their being perpendicular, the homologous sides are the perpendicular ones. Thus in the latter case  $DE$  is homologous with  $AB$ ,  $DF$  with  $AC$ , and  $EF$  with  $BC$ .

The case of the perpendicular sides might present a relative position of the two triangles different from that exhibited in the diagram. But we might always conceive a triangle  $DEF$  to be constructed within the triangle  $ABC$ , and such that its sides should be parallel to those of the triangle compared with  $ABC$ ; and then the demonstration given in the text would apply.

## PROPOSITION XXII. THEOREM.

*In any triangle, if a line be drawn parallel to the base, then, all lines drawn from the vertex will divide the base and the parallel into proportional parts.*

Let  $DE$  be parallel to the base  $BC$ , and the other lines drawn as in the figure ; then will

$$DI : BF :: IK : FG :: KL : GH.$$

For, since  $DI$  is parallel to  $BF$ , the triangles  $ADI$  and  $ABF$  are equiangular ; and we have  $DI : BF :: AI : AF$  ; and since  $IK$  is parallel to  $FG$ , we have in like manner  $AI : AF :: IK : FG$  ; hence, the ratio  $AI : AF$  being common, we shall have  $DI : BF :: IK : FG$ . In the same manner we shall find  $IK : FG :: KL : GH$  ; and so with the other segments : hence the line  $DE$  is divided at the points  $I, K, L$ , in the same proportion, as the base  $BC$ , at the points  $F, G, H$ .

*Cor.* Therefore if  $BC$  were divided into equal parts at the points  $F, G, H$ , the parallel  $DE$  would also be divided into equal parts at the points  $I, K, L$ .

## PROPOSITION XXIII. THEOREM.

*If from the right angle of a right angled triangle, a perpendicular be let fall on the hypotenuse ; then,*

- 1st. *The two partial triangles thus formed, will be similar to each other, and to the whole triangle.*
- 2d. *Either side including the right angle will be a mean proportional between the hypotenuse and the adjacent segment.*
- 3d. *The perpendicular will be a mean proportional between the two segments of the hypotenuse.*

Let  $BAC$  be a right angled triangle, and  $AD$  perpendicular to the hypotenuse  $BC$ .

*First.* The triangles  $BAD$  and  $BAC$  have the common angle  $B$ , the right angle  $BDA = BAC$ , and therefore the third angle  $BAD$  of the one, equal to the third angle  $C$ , of the other (Book I. Prop. XXV. Cor 2.) : hence those two triangles are equiangular and

similar. In the same manner it may be shown that the triangles DAC and BAC are similar; hence all the triangles are equiangular and similar.

*Secondly.* The triangles BAD, BAC, being similar, their homologous sides are proportional. But BD in the small triangle, and BA in the large one, are homologous sides, because they lie opposite the equal angles BAD, BCA; the hypotenuse BA of the small triangle is homologous with the hypotenuse BC of the large triangle: hence the proportion  $BD : BA :: BA : BC$ . By the same reasoning, we should find  $DC : AC :: AC : BC$ ; hence, each of the sides AB, AC, is a mean proportional between the hypotenuse and the segment adjacent to that side.

*Thirdly.* Since the triangles ABD, ADC, are similar, by comparing their homologous sides, we have  $BD : AD :: AD : DC$ ; hence, the perpendicular AD is a mean proportional between the segments BD, DC, of the hypotenuse.

*Scholium.* Since  $BD : AB :: AB : BC$ , the product of the extremes will be equal to that of the means, or  $AB^2 = BD \cdot BC$ . For the same reason we have  $AC^2 = DC \cdot BC$ ; therefore  $AB^2 + AC^2 = BD \cdot BC + DC \cdot BC = (BD + DC) \cdot BC = BC \cdot BC = BC^2$ ; or the square described on the hypotenuse BC is equivalent to the squares described on the two sides AB, AC. Thus we again arrive at the property of the square of the hypotenuse, by a path very different from that which formerly conducted us to it: and thus it appears that, strictly speaking, the property of the square of the hypotenuse, is a consequence of the more general property, that the sides of equiangular triangles are proportional. Thus the fundamental propositions of geometry are reduced, as it were, to this single one, that equiangular triangles have their homologous sides proportional.

It happens frequently, as in this instance, that by deducing consequences from one or more propositions, we are led back to some proposition already proved. In fact, the chief characteristic of geometrical theorems, and one indubitable proof of their certainty is, that, however we combine them together, provided only our reasoning be correct, the results we obtain are always perfectly accurate. The case would be different, if any proposition were false or only approximately true: it would frequently happen that on combining the propositions together, the error would increase and become perceptible. Examples of this are to be seen in all the demonstrations, in which the *reductio ad absurdum* is employed. In such demonstrations, where the object is to show that two quantities are equal, we proceed by showing that if there existed the smallest

inequality between the quantities, a train of accurate reasoning would lead us to a manifest and palpable absurdity; from which we are forced to conclude that the two quantities are equal.

*Cor.* If from a point A, in the circumference of a circle, two chords AB, AC, be drawn to the extremities of a diameter BC, the triangle BAC will be right angled at A (Book III. Prop. XVIII. Cor. 2.); hence, first, *the perpendicular AD is a mean proportional between the two segments BD, DC, of the diameter, or what is the same,  $AD^2 = BD \cdot DC$ .*

Hence also, in the second place, *the chord AB is a mean proportional between the diameter BC and the adjacent segment BD, or, what is the same,  $AB^2 = BD \cdot BC$ .* In like manner, we have  $AC^2 = CD \cdot BC$ ; hence  $AB^2 : AC^2 :: BD : DC$ ; and comparing  $AB^2$  and  $AC^2$ , to  $BC^2$ , we have  $AB^2 : BC^2 :: BD : BC$ , and  $AC^2 : BC^2 :: DC : BC$ . Those proportions between the squares of the sides compared with each other, or with the square of the hypotenuse, have already been given in the third and fourth corollaries of Prop. XI.

#### PROPOSITION XXIV. THEOREM.

*Two triangles having an angle in each equal, are to each other as the rectangles of the sides which contain the equal angles.*

In the two triangles ABC, ADE, let the angle A be equal to the angle A; then will the triangle

$$ABC : ADE :: AB \cdot AC : AD \cdot AE.$$

Draw BE. The triangles ABE, ADE, having the common vertex E, have the same altitude, and consequently are to each other as their bases (Prop. VI. Cor.): that is,

$$ABE : ADE :: AB : AD.$$

In like manner,

$$ABC : ABE :: AC : AE.$$

Multiply together the corresponding terms of these proportions, omitting the common term ABE; we have

$$ABC : ADE : AB \cdot AC : AD \cdot AE.$$

*Cor.* Hence the two triangles would be equivalent, if the rectangle  $AB.AC$  were equal to the rectangle  $AD.AE$ , or if we had  $AB : AD :: AE : AC$ ; which would happen if  $DC$  were parallel to  $BE$ .

PROPOSITION XXV. THEOREM.

*Two similar triangles are to each other as the squares described on their homologous sides.*

Let  $ABC$ ,  $DEF$ , be two similar triangles, having the angle  $A$  equal to  $D$ , and the angle  $B=E$ .

Then, first, by reason of the equal angles  $A$  and  $D$ , according to the last proposition, we shall have

$$ABC : DEF :: AB.AC : DE.DF.$$

Also, because the triangles are similar,

$$AB : DE :: AC : DF,$$

And multiplying the terms of this proportion by the corresponding terms of the identical proportion,

$$AC : DF :: AC : DF,$$

there will result

$$AB.AC : DE.DF :: AC^2 : DF^2.$$

Consequently,

$$ABC : DEF :: AC^2 : DF^2.$$

Therefore, two similar triangles  $ABC$ ,  $DEF$ , are to each other as the squares described on their homologous sides  $AC$ ,  $DF$ , or as the squares of any other two homologous sides.

PROPOSITION XXVI. THEOREM.

*Two similar polygons are composed of the same number of triangles, similar each to each, and similarly situated.*

Let  $ABCDE$ ,  $FGHIK$ , be two similar polygons.

From any angle  $A$ , in the polygon  $ABCDE$ , draw diagonals  $AC$ ,  $AD$  to the other angles. From the homologous angle  $F$ , in the other polygon  $FGHIK$ , draw diagonals  $FH$ ,  $FI$  to the other angles.

These polygons being similar, the angles  $ABC$ ,  $FGH$ , which are homologous, must be equal, and the sides  $AB$ ,  $BC$ , must also be proportional to  $FG$ ,  $GH$ , that is,  $AB : FG :: BC : GH$  (Def. 1.). Wherefore the triangles  $ABC$ ,  $FGH$ , have each an equal angle, contained between proportional sides; hence they are similar (Prop. XX.); therefore the angle  $BCA$  is equal to  $GHF$ . Take away these equal angles from the equal angles  $BCD$ ,  $GHI$ , and there remains  $ACD = FHI$ . But since the triangles  $ABC$ ,  $FGH$ , are similar, we have  $AC : FH :: BC : GH$ ; and, since the polygons are similar,  $BC : GH :: CD : HI$ ; hence  $AC : FH :: CD : HI$ . But the angle  $ACD$ , we already know, is equal to  $FHI$ ; hence the triangles  $ACD$ ,  $FHI$ , have an equal angle in each, included between proportional sides, and are consequently similar (Prop. XX.). In the same manner it might be shown that all the remaining triangles are similar, whatever be the number of sides in the polygons proposed: therefore two similar polygons are composed of the same number of triangles, similar, and similarly situated.

*Scholium.* The converse of the proposition is equally true: *If two polygons are composed of the same number of triangles similar and similarly situated, those two polygons will be similar.*

For, the similarity of the respective triangles will give the angles,  $ABC = FGH$ ,  $BCA = GHF$ ,  $ACD = FHI$ : hence  $BCD = GHI$ , likewise  $CDE = HIK$ , &c. Moreover we shall have  $AB : FG :: BC : GH :: AC : FH :: CD : HI$ , &c.; hence the two polygons have their angles equal and their sides proportional; consequently they are similar.

#### PROPOSITION XXVII. THEOREM.

*The contours or perimeters of similar polygons are to each other as the homologous sides: and the areas are to each other as the squares described on those sides.*

*First.* Since, by the nature of similar figures, we have  $AB : FG :: BC : GH :: CD : HI$ , &c. we conclude from this series of equal ratios that the sum of the antecedents  $AB + BC + CD$ ,

&c., which makes up the perimeter of the first polygon, is to the sum of the consequents  $FG + GH + HI$ , &c., which makes up the perimeter of the second polygon, as any one antecedent is to its consequent; and therefore, as the side  $AB$  is to its corresponding side  $FG$  (Book II. Prop. X.).

*Secondly.* Since the triangles  $ABC$ ,  $FGH$  are similar, we shall have the triangle  $ABC : FGH :: AC^2 : FH^2$  (Prop. XXV.); and in like manner, from the similar triangles  $ACD$ ,  $FHI$ , we shall have  $ACD : FHI :: AC^2 : FH^2$ ; therefore, by reason of the common ratio,  $AC^2 : FH^2$ , we have

$$ABC : FGH :: ACD : FHI.$$

By the same mode of reasoning, we should find

$$ACD : FHI :: ADE : FIK;$$

and so on, if there were more triangles. And from this series of equal ratios, we conclude that the sum of the antecedents  $ABC + ACD + ADE$ , or the polygon  $ABCDE$ , is to the sum of the consequents  $FGH + FHI + FIK$ , or to the polygon  $FGHIK$ , as one antecedent  $ABC$ , is to its consequent  $FGH$ , or as  $AB^2$  is to  $FG^2$  (Prop. XXV.); hence the areas of similar polygons are to each other as the squares described on the homologous sides.

*Cor.* If three similar figures were constructed, on the three sides of a right angled triangle, the figure on the hypotenuse would be equivalent to the sum of the other two: for the three figures are proportional to the squares of their homologous sides; but the square of the hypotenuse is equivalent to the sum of the squares of the two other sides; hence, &c.

#### PROPOSITION XXVIII. THEOREM.

*The segments of two chords, which intersect each other in a circle, are reciprocally proportional.*

Let the chords AB and CD intersect at O : then will

$$AO : DO :: OC : OB.$$

Draw AC and BD. In the triangles ACO, BOD, the angles at O are equal, being vertical ; the angle A is equal to the angle D, because both are inscribed in the same segment (Book III. Prop. XVIII. Cor. 1.) ; for the same reason the angle C=B ; the triangles are therefore similar, and the homologous sides give the proportion

$$AO : DO :: CO : OB.$$

*Cor.* Therefore  $AO.OB=DO.CO$  : hence the rectangle under the two segments of the one chord is equal to the rectangle under the two segments of the other.

#### PROPOSITION XXIX. THEOREM.

*If from the same point without a circle, two secants be drawn terminating in the concave arc, the whole secants will be reciprocally proportional to their external segments.*

Let the secants OB, OC, be drawn from the point O : then will

$$OB : OC :: OD : OA.$$

For, drawing AC, BD, the triangles OAC, OBD have the angle O common ; likewise the angle B=C (Book III. Prop. XVIII. Cor. 1.) ; these triangles are therefore similar ; and their homologous sides give the proportion,

$$OB : OC :: OD : OA.$$

*Cor.* Hence the rectangle  $OA.OB$  is equal to the rectangle  $OC.OD$ .

*Scholium.* This proposition, it may be observed, bears a great analogy to the preceding, and differs from it only as the two chords AB, CD, instead of intersecting each other within, cut each other without the circle. The following proposition may also be regarded as a particular case of the proposition just demonstrated.

PROPOSITION XXX. THEOREM.

*If from the same point without a circle, a tangent and a secant be drawn, the tangent will be a mean proportional between the secant and its external segment.*

From the point O, let the tangent OA, and the secant OC be drawn; then will

$$OC : OA :: OA : OD, \text{ or } OA^2 = OC \cdot OD.$$

For, drawing AD and AC, the triangles OAD, OAC, have the angle O common; also the angle OAD, formed by a tangent and a chord, has for its measure half of the arc AD (Book III. Prop. XXI.); and the angle C has the same measure: hence the angle OAD = C; therefore the two triangles are similar, and we have the proportion  $OC : OA :: OA : OD$ , which gives  $OA^2 = OC \cdot OD$ .

PROPOSITION XXXI. THEOREM.

*If either angle of a triangle be bisected by a line terminating in the opposite side, the rectangle of the sides including the bisected angle, is equivalent to the square of the bisecting line together with the rectangle contained by the segments of the third side.*

In the triangle BAC, let AD bisect the angle A; then will  
 $AB \cdot AC = AD^2 + BD \cdot DC$ .

Describe a circle through the three points A, B, C; produce AD till it meets the circumference, and draw CE.

The triangle BAD is similar to the triangle EAC; for, by hypothesis, the angle BAD = EAC; also the angle B = E, since they are both measured by half of the arc AC; hence these triangles are similar, and the homologous sides give the proportion  $BA : AE :: AD : AC$ ; hence  $BA \cdot AC = AE \cdot AD$ ; but  $AE = AD + DE$ , and multiplying each of these equals by AD, we have  $AE \cdot AD = AD^2 + AD \cdot DE$ ; now  $AD \cdot DE = BD \cdot DC$  (Prop. XXVIII.); hence, finally,

$$BA \cdot AC = AD^2 + BD \cdot DC.$$

## PROPOSITION XXXII. THEOREM

*In every triangle, the rectangle contained by two sides is equivalent to the rectangle contained by the diameter of the circumscribed circle, and the perpendicular let fall upon the third side.*

In the triangle  $ABC$ , let  $AD$  be drawn perpendicular to  $BC$ ; and let  $EC$  be the diameter of the circumscribed circle; then will

$$AB.AC = AD.CE.$$

For, drawing  $AE$ , the triangles  $ABD$ ,  $AEC$ , are right angled, the one at  $D$ , the other at  $A$ : also the angle  $B = E$ ; these triangles are therefore similar, and they give the proportion  $AB : CE :: AD : AC$ ; and hence  $AB.AC = CE.AD$ .

*Cor.* If these equal quantities be multiplied by the same quantity  $BC$ , there will result  $AB.AC.BC = CE.AD.BC$ ; now  $AD.BC$  is double of the area of the triangle (Prop. VI.); therefore *the product of three sides of a triangle is equal to its area multiplied by twice the diameter of the circumscribed circle.*

The product of three lines is sometimes called a *solid*, for a reason that shall be seen afterwards. Its value is easily conceived, by imagining that the lines are reduced into numbers, and multiplying these numbers together.

*Scholium.* It may also be demonstrated, that the area of a triangle is equal to its perimeter multiplied by half the radius of the inscribed circle.

For, the triangles  $AOB$ ,  $BOC$ ,  $AOC$ , which have a common vertex at  $O$ , have for their common altitude the radius of the inscribed circle; hence the sum of these triangles will be equal to the sum of the bases  $AB$ ,  $BC$ ,  $AC$ , multiplied by half the radius

$OD$ ; hence the area of the triangle  $ABC$  is equal to the perimeter multiplied by half the radius of the inscribed circle

## PROPOSITION XXXIII. THEOREM.

*In every quadrilateral inscribed in a circle, the rectangle of the two diagonals is equivalent to the sum of the rectangles of the opposite sides.*

In the quadrilateral ABCD, we shall have

$$AC.BD = AB.CD + AD.BC.$$

Take the arc  $CO = AD$ , and draw BO meeting the diagonal AC in I.

The angle  $ABD = CBI$ , since the one has for its measure half of the arc AD, and the other, half of CO, equal to AD; the angle  $ADB = BCI$ , because they are both inscribed in the same segment AOB; hence the triangle ABD is similar to the triangle IBC, and we have the proportion  $AD : CI :: BD : BC$ ; hence  $AD.BC = CI.BD$ . Again, the triangle ABI is similar to the triangle BDC; for the arc AD being equal to CO, if OD be added to each of them, we shall have the arc  $AO = DC$ ; hence the angle ABI is equal to DBC; also the angle BAI to BDC, because they are inscribed in the same segment; hence the triangles ABI, DBC, are similar, and the homologous sides give the proportion  $AB : BD :: AI : CD$ ; hence  $AB.CD = AI.BD$ .

Adding the two results obtained, and observing that

$$AI.BD + CI.BD = (AI + CI).BD = AC.BD,$$

we shall have

$$AD.BC + AB.CD = AC.BD.$$

## PROBLEMS RELATING TO THE FOURTH BOOK.

## PROBLEM I.

*To divide a given straight line into any number of equal parts, or into parts proportional to given lines.*

*First.* Let it be proposed to divide the line AB into five equal parts. Through the extremity A, draw the indefinite straight line AG; and taking AC of any magnitude, apply it five times upon AG; join the last point of division G, and the extremity B, by the straight line GB; then draw CI parallel to GB: AI will be the fifth part of the line AB; and thus, by applying AI five times upon AB, the line AB will be divided into five equal parts.

For, since CI is parallel to GB, the sides AG, AB, are cut proportionally in C and I (Prop. XV.). But AC is the fifth part of AG, hence AI is the fifth part of AB,

*Secondly.* Let it be proposed to divide the line AB into parts proportional to the given lines P, Q, R. Through A, draw the indefinite line AG; make AC = P, CD = Q, DE = R; join the extremities E and B; and through the points C, D, draw CI, DF, parallel to EB; the line AB will be divided into parts AI, IF, FB, proportional to the given lines P, Q, R.

For, by reason of the parallels CI, DF, EB, the parts AI, IF, FB, are proportional to the parts AC, CD, DE; and by construction, these are equal to the given lines P, Q, R.

## PROBLEM II.

*To find a fourth proportional to three given lines, A, B, C.*

Draw the two indefinite lines DE, DF, forming any angle with each other. Upon DE take  $DA=A$ , and  $DB=B$ ; upon DF take  $DC=C$ ; draw AC; and through the point B, draw BX parallel to AC; DX will be the fourth proportional required; for, since BX is parallel to AC, we have the proportion  $DA : DB :: DC : DX$ ; now the first three terms of this proportion are equal to the three given lines: consequently DX is the fourth proportional required.

*Cor.* A third proportional to two given lines A, B, may be found in the same manner, for it will be the same as a fourth proportional to the three lines A, B, B.

## PROBLEM III.

*To find a mean proportional between two given lines A and B.*

Upon the indefinite line DF, take  $DE=A$ , and  $EF=B$ ; upon the whole line DF, as a diameter, describe the semicircle DGF; at the point E, erect upon the diameter the perpendicular EG meeting the circumference in G; EG will be the mean proportional required.

For, the perpendicular EG, let fall from a point in the circumference upon the diameter, is a mean proportional between DE, EF, the two segments of the diameter (Prop. XXIII. Cor.); and these segments are equal to the given lines A and B.

## PROBLEM IV.

*To divide a given line into two parts, such that the greater part shall be a mean proportional between the whole line and the other part.*

Let  $AB$  be the given line.

At the extremity  $B$  of the line  $AB$ , erect the perpendicular  $BC$  equal to the half of  $AB$ ; from the point  $C$ , as a centre, with the radius  $CB$ , describe a semicircle; draw  $AC$  cutting the circumference in  $D$ ; and take  $AF=AD$ : the line  $AB$  will be divided at the point  $F$  in the manner required; that is, we shall have  $AB : AF :: AF : FB$ .

For,  $AB$  being perpendicular to the radius at its extremity, is a tangent; and if  $AC$  be produced till it again meets the circumference in  $E$ , we shall have  $AE : AB :: AB : AD$  (Prop. XXX.); hence, by division,  $AE - AB : AB :: AB - AD : AD$ . But since the radius is the half of  $AB$ , the diameter  $DE$  is equal to  $AB$ , and consequently  $AE - AB = AD = AF$ ; also, because  $AF = AD$ , we have  $AB - AD = FB$ ; hence  $AF : AB :: FB : AD$  or  $AF$ ; whence, by exchanging the extremes for the means,  $AB : AF :: AF : FB$ .

*Scholium.* This sort of division of the line  $AB$  is called division in extreme and mean ratio: the use of it will be perceived in a future part of the work. It may further be observed, that the secant  $AE$  is divided in extreme and mean ratio at the point  $D$ ; for, since  $AB = DE$ , we have  $AE : DE :: DE : AD$ .

#### PROBLEM V.

*Through a given point, in a given angle, to draw a line so that the segments comprehended between the point and the two sides of the angle, shall be equal.*

Let  $BCD$  be the given angle, and  $A$  the given point.

Through the point  $A$ , draw  $AE$  parallel to  $CD$ , make  $BE = CE$ , and through the points  $B$  and  $A$  draw  $BAD$ ; this will be the line required.

For,  $AE$  being parallel to  $CD$ , we have  $BE : EC :: BA : AD$ ; but  $BE = EC$ ; therefore  $BA = AD$ .

## PROBLEM VI.

*To describe a square that shall be equivalent to a given parallelogram, or to a given triangle.*

*First.* Let ABCD be the given parallelogram, AB its base, DE its altitude: between AB and DE find a mean proportional XY; then will the square described upon XY be equivalent to the parallelogram ABCD.

For, by construction,  $AB : XY :: XY : DE$ ; therefore,  $XY^2 = AB \cdot DE$ ; but  $AB \cdot DE$  is the measure of the parallelogram, and  $XY^2$  that of the square; consequently, they are equivalent.

*Secondly.* Let ABC be the given triangle, BC its base, AD its altitude: find a mean proportional between BC and the half of AD, and let XY be that mean; the square described upon XY will be equivalent to the triangle ABC.

For, since  $BC : XY :: XY : \frac{1}{2}AD$ , it follows that  $XY^2 = BC \cdot \frac{1}{2}AD$ ; hence the square described upon XY is equivalent to the triangle ABC.

## PROBLEM VII.

*Upon a given line, to describe a rectangle that shall be equivalent to a given rectangle.*

Let AD be the line, and ABFC the given rectangle.

Find a fourth proportional to the three lines AD, AB, AC, and let AX be that fourth proportional; a rectangle constructed with the lines AD and AX will be equivalent to the rectangle ABFC.

For, since  $AD : AB :: AC : AX$ , it follows that  $AD \cdot AX = AB \cdot AC$ ; hence the rectangle ADEX is equivalent to the rectangle ABFC.

## PROBLEM VIII.

*To find two lines whose ratio shall be the same as the ratio of two rectangles contained by given lines.*

Let A.B, C.D, be the rectangles contained by the given lines A, B, C, and D.

Find X, a fourth proportional to the three lines B, C, D; then will the two lines A and X have the same ratio to each other as the rectangles A.B and C.D.

For, since  $B : C :: D : X$ , it follows that  $C.D = B.X$ ; hence  $A.B : C.D :: A.B : B.X :: A : X$ .

*Cor.* Hence to obtain the ratio of the squares described upon the given lines A and C, find a third proportional X to the lines A and C, so that  $A : C :: C : X$ ; you will then have

$$A.X = C^2, \text{ or } A^2.X = A.C^2; \text{ hence } A^2 : C^2 :: A : X.$$

## PROBLEM IX.

*To find a triangle that shall be equivalent to a given polygon.*

Let ABCDE be the given polygon. Draw first the diagonal CE cutting off the triangle CDE; through the point D, draw DF parallel to CE, and meeting AE produced; draw CF: the polygon ABCDE will be equivalent to the polygon ABCF, which has one side less than the original polygon.

For, the triangles CDE, CFE, have the base CE common, they have also the same altitude, since their vertices D and F, are situated in a line DF parallel to the base: these triangles are therefore equivalent (Prop. II. Cor. 2.). Add to each of them the figure ABCE, and there will result the polygon ABCDE, equivalent to the polygon ABCF.

The angle B may in like manner be cut off, by substituting for the triangle ABC the equivalent triangle AGC, and thus the pentagon ABCDE will be changed into an equivalent triangle GCF.

The same process may be applied to every other figure; for, by successively diminishing the number of its sides, one being retrenched at each step of the process, the equivalent triangle will at last be found.

*Scholium.* We have already seen that every triangle may be changed into an equivalent square (Prob. VI.); and thus a square may always be found equivalent to a given rectilineal figure, which operation is called *squaring* the rectilineal figure, or finding the *quadrature* of it.

The problem of the *quadrature of the circle*, consists in finding a square equivalent to a circle whose diameter is given.

## PROBLEM X.

*To find the side of a square which shall be equivalent to the sum or the difference of two given squares.*

Let  $A$  and  $B$  be the sides of the given squares.

*First.* If it is required to find a square equivalent to the sum of these squares, draw the two indefinite lines  $ED$ ,  $EF$ , at right angles to each other; take  $ED=A$ , and  $EG=B$ ; draw  $DG$ : this will be the side of the square required.

For the triangle  $DEG$  being right angled, the square described upon  $DG$  is equivalent to the sum of the squares upon  $ED$  and  $EG$ .

*Secondly.* If it is required to find a square equivalent to the difference of the given squares, form in the same manner the right angle  $FEH$ ; take  $GE$  equal to the shorter of the sides  $A$  and  $B$ ; from the point  $G$  as a centre, with a radius  $GH$ , equal to the other side, describe an arc cutting  $EH$  in  $H$ : the square described upon  $EH$  will be equivalent to the difference of the squares described upon the lines  $A$  and  $B$ .

For the triangle  $GEH$  is right angled, the hypotenuse  $GH=A$ , and the side  $GE=B$ ; hence the square described upon  $EH$ , is equivalent to the difference of the squares  $A$  and  $B$ .

*Scholium.* A square may thus be found, equivalent to the sum of any number of squares; for a similar construction which reduces two of them to one, will reduce three of them to two, and these two to one, and so of others. It would be the same, if any of the squares were to be subtracted from the sum of the others.

## PROBLEM XI.

*To find a square which shall be to a given square as a given line to a given line.*

Let AC be the given square, and M and N the given lines.

Upon the indefinite line EG, take  $EF=M$ , and  $FG=N$ ; upon EG as a diameter describe a semicircle, and at the point F erect the perpendicular FH. From the point H, draw the chords HG, HE, which produce indefinitely: upon the first, take HK equal to the side AB of the given square, and through the point K draw KI parallel to EG; HI will be the side of the square required.

For, by reason of the parallels KI, GE, we have  $HI : HK :: HE : HG$ ; hence,  $HI^2 : HK^2 :: HE^2 : HG^2$ ; but in the right angled triangle EHG, the square of HE is to the square of HG as the segment EF is to the segment FG (Prop. XI. Cor. 3.), or as M is to N; hence  $HI^2 : HK^2 :: M : N$ . But  $HK=AB$ ; therefore the square described upon HI is to the square described upon AB as M is to N.

## PROBLEM XII.

*Upon a given line, to describe a polygon similar to a given polygon.*

Let FG be the given line, and AEDCB the given polygon.

In the given polygon, draw the diagonals AC, AD; at the point F make the angle GFH = BAC, and at the point G the angle FGH = ABC; the lines FH, GH will cut each other in H, and FGH will be a triangle similar to ABC. In the same manner upon FH, homologous to AC, describe the triangle FHI similar to ADC; and upon FI, homologous to AD, describe the triangle FIK similar to ADE. The polygon FGHIK will be similar to ABCDE, as required.

For, these two polygons are composed of the same number of triangles, which are similar and similarly situated (Prop. XXVI. Sch.).

## PROBLEM XIII.

*Two similar figures being given, to describe a similar figure which shall be equivalent to their sum or their difference.*

Let A and B be two homologous sides of the given figures.

Find a square equivalent to the sum or to the difference of the squares described upon A and B; let X be the side of that square; then will X in the figure required, be the side which is homologous to the sides A and B in the given figures. The figure itself may then be constructed on X, by the last problem.

For, the similar figures are as the squares of their homologous sides; now the square of the side X is equivalent to the sum, or to the difference of the squares described upon the homologous sides A and B; therefore the figure described upon the side X is equivalent to the sum, or to the difference of the similar figures described upon the sides A and B.

## PROBLEM XIV.

*To describe a figure similar to a given figure, and bearing to it the given ratio of M to N.*

Let A be a side of the given figure, X the homologous side of the figure required. The square of X must be to the square of A, as M is to N: hence X will be found by (Prob. XI.), and knowing X, the rest will be accomplished by (Prob. XII.).

## PROBLEM XV.

*To construct a figure similar to the figure P, and equivalent to the figure Q.*

Find M, the side of a square equivalent to the figure P, and N, the side of a square equivalent to the figure Q. Let X be a fourth proportional to the three given lines, M, N, AB; upon the side X, homologous to AB, describe a figure similar to the figure P; it will also be equivalent to the figure Q.

For, calling Y the figure described upon the side X, we have  $P : Y :: AB^2 : X^2$ ; but by construction,  $AB : X :: M : N$ , or  $AB^2 : X^2 :: M^2 : N^2$ ; hence  $P : Y :: M^2 : N^2$ . But by construction also,  $M^2 = P$  and  $N^2 = Q$ ; therefore  $P : Y :: P : Q$ ; consequently  $Y = Q$ ; hence the figure Y is similar to the figure P, and equivalent to the figure Q.

## PROBLEM XVI.

*To construct a rectangle equivalent to a given square, and having the sum of its adjacent sides equal to a given line.*

Let C be the square, and AB equal to the sum of the sides of the required rectangle.

Upon AB as a diameter, describe a semicircle; draw the line DE parallel to the diameter, at a distance AD from it, equal to the side of the given square C; from the point E, where the parallel cuts the circumference, draw EF perpendicular to the diameter; AF and FB will be the sides of the rectangle required.

For their sum is equal to AB; and their rectangle AF.FB is equivalent to the square of EF, or to the square of AD; hence that rectangle is equivalent to the given square C.

*Scholium.* To render the problem possible, the distance AD must not exceed the radius; that is, the side of the square C must not exceed the half of the line AB.

## PROBLEM XVII.

*To construct a rectangle that shall be equivalent to a given square, and the difference of whose adjacent sides shall be equal to a given line.*

Suppose  $C$  equal to the given square, and  $AB$  the difference of the sides.

Upon the given line  $AB$  as a diameter, describe a semicircle: at the extremity of the diameter draw the tangent  $AD$ , equal to the side of the square  $C$ ; through the point  $D$  and the centre  $O$  draw the secant  $DF$ ; then will  $DE$  and  $DF$  be the adjacent sides of the rectangle required.

For, first, the difference of these sides is equal to the diameter  $EF$  or  $AB$ ; secondly, the rectangle  $DE, DF$ , is equal to  $AD^2$  (Prop. XXX.); hence that rectangle is equivalent to the given square  $C$ .

## PROBLEM XVIII.

*To find the common measure, if there is one, between the diagonal and the side of a square.*

Let  $ABCG$  be any square whatever, and  $AC$  its diagonal.

We must first apply  $CB$  upon  $CA$ , as often as it may be contained there. For this purpose, let the semicircle  $DBE$  be described, from the centre  $C$ , with the radius  $CB$ . It is evident that  $CB$  is contained once in  $AC$ , with the remainder  $AD$ ; the result of the first operation

is therefore the quotient 1, with the remainder  $AD$ , which latter must now be compared with  $BC$ , or its equal  $AB$ .

We might here take  $AF=AD$ , and actually apply it upon  $AB$ ; we should find it to be contained twice with a remainder: but as that remainder, and those which succeed it, con-

tinue diminishing, and would soon elude our comparisons by their minuteness, this would be but an imperfect mechanical method, from which no conclusion could be obtained to determine whether the lines AC, CB, have or have not a common measure. There is a very simple way, however, of avoiding these decreasing lines, and obtaining the result, by operating

only upon lines which remain always of the same magnitude.

The angle ABC being a right angle, AB is a tangent, and AE a secant drawn from the same point; so that  $AD : AB :: AB : AE$  (Prop. XXX.). Hence in the second operation, when AD is compared with AB, the ratio of AB to AE may be taken instead of that of AD to AB; now AB, or its equal CD, is contained twice in AE, with the remainder AD; the result of the second operation is therefore the quotient 2 with the remainder AD, which must be compared with AB.

Thus the third operation again consists in comparing AD with AB, and may be reduced in the same manner to the comparison of AB or its equal CD with AE; from which there will again be obtained 2 for the quotient, and AD for the remainder.

Hence, it is evident that the process will never terminate; and therefore there is no common measure between the diagonal and the side of a square: a truth which was already known by arithmetic, since these two lines are to each other  $:: \sqrt{2} : 1$  (Prop. XI. Cor. 4.), but which acquires a greater degree of clearness by the geometrical investigation.

## BOOK V.

## REGULAR POLYGONS, AND THE MEASUREMENT OF THE CIRCLE.

*Definition.*

A POLYGON, which is at once equilateral and equiangular, is called a *regular polygon*.

Regular polygons may have any number of sides: the equilateral triangle is one of three sides; the square is one of four.

## PROPOSITION I. THEOREM.

*Two regular polygons of the same number of sides are similar figures.*

Suppose, for example, that  $ABCDEF$ ,  $abcdef$ , are two regular hexagons. The sum of all the angles is the same in both figures, being in each equal to eight right angles (Book I. Prop. XXVI. Cor. 3.). The angle  $A$  is the sixth part of that sum; so is the angle  $a$ : hence the angles  $A$  and  $a$  are equal; and for the same reason, the angles  $B$  and  $b$ , the angles  $C$  and  $c$ , &c. are equal.

Again, since the polygons are regular, the sides  $AB$ ,  $BC$ ,  $CD$ , &c. are equal, and likewise the sides  $ab$ ,  $bc$ ,  $cd$ , &c. (Def.); it is plain that  $AB : ab :: BC : bc :: CD : cd$ , &c.; hence the two figures in question have their angles equal, and their homologous sides proportional; consequently they are similar (Book IV. Def. 1.).

*Cor.* The perimeters of two regular polygons of the same number of sides, are to each other as their homologous sides, and their surfaces are to each other as the squares of those sides (Book IV. Prop. XXVII.).

*Scholium.* The angle of a regular polygon, like the angle of an equiangular polygon, is determined by the number of its sides (Book I. Prop. XXVI.).

## PROPOSITION II. THEOREM.

*Any regular polygon may be inscribed in a circle, and circumscribed about one.*

Let  $ABCDE$  &c. be a regular polygon : describe a circle through the three points  $A, B, C$ , the centre being  $O$ , and  $OP$  the perpendicular let fall from it, to the middle point of  $BC$  : draw  $AO$  and  $OD$ .

If the quadrilateral  $OPCD$  be placed upon the quadrilateral  $OPBA$ , they will coincide ; for the side  $OP$  is common ; the angle  $OPC = OPB$ , each being a right angle ; hence the side  $PC$  will apply to its equal  $PB$ , and the point  $C$  will fall on  $B$  : besides, from the nature of the polygon, the angle  $PCD = PBA$  ; hence  $CD$  will take the direction  $BA$  ; and since  $CD = BA$ , the point  $D$  will fall on  $A$ , and the two quadrilaterals will entirely coincide. The distance  $OD$  is therefore equal to  $AO$  ; and consequently the circle which passes through the three points  $A, B, C$ , will also pass through the point  $D$ . By the same mode of reasoning, it might be shown, that the circle which passes through the three points  $B, C, D$ , will also pass through the point  $E$  ; and so of all the rest : hence the circle which passes through the points  $A, B, C$ , passes also through the vertices of all the angles in the polygon, which is therefore inscribed in this circle.

Again, in reference to this circle, all the sides  $AB, BC, CD$ , &c. are equal chords ; they are therefore equally distant from the centre (Book III. Prop. VIII.) : hence, if from the point  $O$  with the distance  $OP$ , a circle be described, it will touch the side  $BC$ , and all the other sides of the polygon, each in its middle point, and the circle will be inscribed in the polygon, or the polygon described about the circle.

*Scholium 1.* The point  $O$ , the common centre of the inscribed and circumscribed circles, may also be regarded as the centre of the polygon ; and upon this principle the angle  $AOB$  is called *the angle at the centre*, being formed by two radii drawn to the extremities of the same side  $AB$ .

Since all the chords  $AB, BC, CD$ , &c. are equal, all the angles at the centre must evidently be equal likewise ; and therefore the value of each will be found by dividing four right angles by the number of sides of the polygon.

*Scholium 2.* To inscribe a regular polygon of a certain number of sides in a given circle, we have only to divide the circumference into as many equal parts as the polygon has sides: for the arcs being equal, the chords AB, BC, CD, &c. will also be equal; hence likewise the triangles AOB, BOC, COD, must be equal, because the sides are equal each to each; hence all the angles ABC, BCD, CDE, &c. will be equal; hence the figure ABCDEH, will be a regular polygon.

PROPOSITION III. PROBLEM.

*To inscribe a square in a given circle.*

Draw two diameters AC, BD, cutting each other at right angles; join their extremities A, B, C, D: the figure ABCD will be a square. For the angles AOB, BOC, &c. being equal, the chords AB, BC, &c. are also equal: and the angles ABC, BCD, &c. being in semicircles, are right angles.

*Scholium.* Since the triangle BCO is right angled and isosceles, we have  $BC : BO :: \sqrt{2} : 1$  (Book IV. Prop. XI. Cor. 4.); hence *the side of the inscribed square is to the radius, as the square root of 2, is to unity.*

PROPOSITION IV. PROBLEM.

*In a given circle, to inscribe a regular hexagon and an equilateral triangle.*

Suppose the problem solved, and that  $AB$  is a side of the inscribed hexagon; the radii  $AO$ ,  $OB$  being drawn, the triangle  $AOB$  will be equilateral.

For, the angle  $AOB$  is the sixth part of four right angles; therefore, taking the right angle for unity, we shall have  $AOB = \frac{4}{6} = \frac{2}{3}$ ; and the two other angles  $ABO$ ,  $BAO$ , of the same triangle, are together equal to  $2 - \frac{2}{3} = \frac{4}{3}$ ; and being mutually equal, each of them must be equal to  $\frac{2}{3}$ ; hence the triangle  $ABO$  is equilateral; therefore the side of the inscribed hexagon is equal to the radius.

Hence to inscribe a regular hexagon in a given circle, the radius must be applied six times to the circumference; which will bring us round to the point of beginning.

And the hexagon  $ABCDEF$  being inscribed, the equilateral triangle  $ACE$  may be formed by joining the vertices of the alternate angles.

*Scholium.* The figure  $ABCO$  is a parallelogram and even a rhombus, since  $AB=BC=CO=AO$ ; hence the sum of the squares of the diagonals  $AC^2 + BO^2$  is equivalent to the sum of the squares of the sides, that is, to  $4AB^2$ , or  $4BO^2$  (Book IV. Prop XIV. Cor.): and taking away  $BO^2$  from both, there will remain  $AC^2 = 3BO^2$ ; hence  $AC^2 : BO^2 :: 3 : 1$ , or  $AC : BO :: \sqrt{3} : 1$ ; hence the side of the inscribed equilateral triangle is to the radius as the square root of three is to unity.

#### PROPOSITION V. PROBLEM.

*In a given circle, to inscribe a regular decagon; then a pentagon, and also a regular polygon of fifteen sides.*

Divide the radius AO in extreme and mean ratio at the point M (Book IV. Prob. IV.); take the chord AB equal to OM the greater segment; AB will be the side of the regular decagon, and will require to be applied ten times to the circumference.

For, drawing MB, we have by construction,  $AO : OM :: OM : AM$ ; or, since  $AB = OM$ ,  $AO : AB :: AB :$

AM; since the triangles ABO, AMB, have a common angle A, included between proportional sides, they are similar (Book IV. Prop. XX.). Now the triangle OAB being isosceles, AMB must be isosceles also, and  $AB=BM$ ; but  $AB=OM$ ; hence also  $MB=OM$ ; hence the triangle BMO is isosceles.

Again, the angle  $AMB$  being exterior to the isosceles triangle  $BMO$ , is double of the interior angle  $O$  (Book I. Prop. XXV. Cor. 6.) : but the angle  $AMB = MAB$  ; hence the triangle  $OAB$  is such, that each of the angles  $OAB$  or  $OBA$ , at its base, is double of  $O$ , the angle at its vertex ; hence the three angles of the triangle are together equal to five times the angle  $O$ , which consequently is the fifth part of the two right angles, or the tenth part of four ; hence the arc  $AB$  is the tenth part of the circumference, and the chord  $AB$  is the side of the regular decagon.

2d. By joining the alternate corners of the regular decagon, the pentagon ACEGI will be formed, also regular.

3d. AB being still the side of the decagon, let AL be the side of a hexagon; the arc BL will then, with reference to the whole circumference, be  $\frac{1}{6} - \frac{1}{10}$ , or  $\frac{1}{15}$ ; hence the chord BL will be the side of the regular polygon of fifteen sides, or pentadecagon. It is evident also, that the arc CL is the third of CB.

*Scholium.* Any regular polygon being inscribed, if the arcs subtended by its sides be severally bisected, the chords of those semi-arcs will form a new regular polygon of double the number of sides : thus it is plain, that the square will enable us to inscribe successively regular polygons of 8, 16, 32, &c. sides. And in like manner, by means of the hexagon, regular polygons of 12, 24, 48, &c. sides may be inscribed ; by means of the decagon, polygons of 20, 40, 80, &c. sides ; by means of the pentadecagon, polygons of 30, 60, 120, &c. sides.

It is further evident, that any of the inscribed polygons will be less than the inscribed polygon of double the number of sides, since a part is less than the whole.

H

## PROPOSITION VI. PROBLEM.

*A regular inscribed polygon being given, to circumscribe a similar polygon about the same circle.*

Let CBAFED be a regular polygon.

At T, the middle point of the arc AB, apply the tangent GH, which will be parallel to AB (Book III. Prop. X.); do the same at the middle point of each of the arcs BC, CD, &c.; these tangents, by their intersections, will form the regular circumscribed polygon GHIK &c. similar to the one inscribed.

Since T is the middle point of the arc BTA, and N the middle point of the equal arc BNC, it follows, that  $BT = BN$ ; or that the vertex B of the inscribed polygon, is at the middle point of the arc NBT. Draw OH. The line OH will pass through the point B.

For, the right angled triangles OTH, OHN, having the common hypotenuse OH, and the side  $OT = ON$ , must be equal (Book I. Prop. XVII.), and consequently the angle  $TOH = HON$ , wherefore the line OH passes through the middle point B of the arc TN. For a like reason, the point I is in the prolongation of OC; and so with the rest.

But, since GH is parallel to AB, and HI to BC, the angle  $GHI = ABC$  (Book I. Prop. XXIV.); in like manner  $HIK = BCD$ ; and so with all the rest: hence the angles of the circumscribed polygon are equal to those of the inscribed one. And further, by reason of these same parallels, we have  $GH : AB :: OH : OB$ , and  $HI : BC :: OH : OB$ ; therefore  $GH : AB :: HI : BC$ . But  $AB = BC$ , therefore  $GH = HI$ . For the same reason,  $HI = IK$ , &c.; hence the sides of the circumscribed polygon are all equal; hence this polygon is regular and similar to the inscribed one.

*Cor. 1.* Reciprocally, if the circumscribed polygon GHIK &c. were given, and the inscribed one ABC &c. were required to be deduced from it, it would only be necessary to

draw from the angles G, H, I, &c. of the given polygon, straight lines OG, OH, &c. meeting the circumference in the points A, B, C, &c.; then to join those points by the chords AB, BC, &c.; this would form the inscribed polygon. An easier solution of this problem would be simply to join the points of contact T, N, P, &c. by the chords TN, NP, &c. which likewise would form an inscribed polygon similar to the circumscribed one.

*Cor. 2.* Hence we may circumscribe about a circle any regular polygon, which can be inscribed within it, and conversely.

*Cor. 3.* It is plain that  $NH + HT = HT + TG = HG$ , one of the equal sides of the polygon.

#### PROPOSITION VII. PROBLEM.

*A circle and regular circumscribed polygon being given, it is required to circumscribe the circle by another regular polygon having double the number of sides.*

Let the circle whose centre is P, be circumscribed by the square CDEG: it is required to find a regular circumscribed octagon.

Bisect the arcs AH, HB, BF, FA, and through the middle points *c, d, a, b*, draw tangents to the circle, and produce them till they meet the sides of the square: then will the figure *ApHdB* &c. be a regular octagon.

For, having drawn *Pd, Pa*, let the quadrilateral *PdgB*, be applied to the quadrilateral *PBfa*, so that *PB* shall fall on *PB*. Then, since the angle *dPB* is equal to the angle *BP a*, each being half a right angle, the line *Pd* will fall on its equal *Pa*, and the point *d* on the point *a*. But the angles *Pdg, Paf*, are right angles (Book III. Prop. IX.); hence the line *dg* will take the direction *af*. The angles *PBg, PBf*, are also right angles; hence *Bg* will take the direction *Bf*; therefore, the two quadrilaterals will coincide, and the point *g* will fall at *f*; hence,  $Bg = Bf$ ,  $dg = af$ , and the angle  $dgB = Bfa$ . By applying in a similar manner, the quadrilaterals *PBfa, PFha*, it may be shown, that  $af = ah$ ,  $fB = Fh$ , and the angle  $Bfa = ahF$ . But since the two tangents *fa, fB*, are

equal (Book III. Prob. XIV. Sch.), it follows that  $fh$ , which is twice  $fa$ , is equal to  $fg$ , which is twice  $fB$ .

In a similar manner it may be shown that  $hf=hi$ , and the angle  $Fit=Fha$ , or that any two sides or any two angles of the octagon are equal: hence the octagon is a regular polygon (Def.). The construction which has been made in the case of the square and the octagon, is equally applicable to other polygons.

*Cor* It is evident that the circumscribed square is greater than the circumscribed octagon by the four triangles,  $Cnp$ ,  $kDg$ ,  $hEf$ ,  $Git$ ; and if a regular polygon of sixteen sides be circumscribed about the circle, we may prove in a similar way, that the figure having the greatest number of sides will be the least; and the same may be shown, whatever be the number of sides of the polygons: hence, in general, *any circumscribed regular polygon, will be greater than a circumscribed regular polygon having double the number of sides.*

#### PROPOSITION VIII. THEOREM.

*Two regular polygons, of the same number of sides, can always be formed, the one circumscribed about a circle, the other inscribed in it, which shall differ from each other by less than any assignable surface.*

Let  $Q$  be the side of a square less than the given surface. Bisect  $AC$ , a fourth part of the circumference, and then bisect the half of this fourth, and proceed in this manner, always bisecting one of the arcs formed by the last bisection, until an arc is found whose chord  $AB$  is less than  $Q$ . As this arc will be an exact part of the circumference, if we apply chords  $AB$ ,  $BC$ ,  $CD$ , &c. each equal to  $AB$ , the last will terminate at  $A$ , and there will be formed a regular polygon  $ABCDE$  &c. in the circle.

Next, describe about the circle a similar polygon  $abcde$  &c. (Prop. VI.): the difference of these two polygons will be less than the square of  $Q$ .

For, from the points  $a$  and  $b$ , draw the lines  $aO$ ,  $bO$ , to the centre  $O$ : they will pass through the points  $A$  and  $B$ , as was

shown in Prop. VI. Draw also OK to the point of contact K : it will bisect AB in I, and be perpendicular to it (Book III. Prop. VI. Sch.). Produce AO to E, and draw BE.

Let P represent the circumscribed polygon, and  $p$  the inscribed polygon : then, since the triangles  $aOb$ , AOB, are like parts of P and  $p$ , we shall have

$$aOb : AOB :: P : p \text{ (Book II. Prop. XI.)} :$$

But the triangles being similar,

$$aOb : AOB :: Oa^2 : OA^2, \text{ or } OK^2.$$

Hence,  $P : p :: Oa^2 : OK^2.$

Again, since the triangles OaK, EAB are similar, having their sides respectively parallel,

$$Oa^2 : OK^2 :: AE^2 : EB^2, \text{ hence,}$$

$$P : p :: AE^2 : EB^2, \text{ or by division,}$$

$$P : P-p :: AE^2 : AE^2 - EB^2, \text{ or } AB^2.$$

But P is less than the square described on the diameter AE (Prop. VII. Cor.); therefore  $P-p$  is less than the square described on AB; that is, less than the given square on Q : hence the difference between the circumscribed and inscribed polygons may always be made less than a given surface.

*Cor. 1.* A circumscribed regular polygon, having a given number of sides, is greater than the circle, because the circle makes up but a part of the polygon : and for a like reason, the inscribed polygon is less than the circle. But by increasing the number of sides of the circumscribed polygon, the polygon is diminished (Prop. VII. Cor.), and therefore approaches to an equality with the circle ; and as the number of sides of the inscribed polygon is increased, the polygon is increased (Prop. V. Sch.), and therefore approaches to an equality with the circle.

Now, *if the number of sides of the polygons be indefinitely increased, the length of each side will be indefinitely small, and the polygons will ultimately become equal to each other, and equal also to the circle.*

For, if they are not ultimately equal, let D represent their smallest difference.

Now, it has been proved in the proposition, that the difference between the circumscribed and inscribed polygons, can be made less than any assignable quantity : that is, less than D : hence the difference between the polygons is equal to D, and less than D at the same time, which is absurd : therefore, the polygons are ultimately equal. But when they are equal to each other, each must also be equal to the circle, since the circumscribed polygon cannot fall within the circle, nor the inscribed polygon without it.

*Cor. 2.* Since the circumscribed polygon has the same number of sides as the corresponding inscribed polygon, and since the two polygons are regular, they will be similar (Prop. I.) ; and therefore when they become equal, they will exactly coincide, and have a common perimeter. But as the sides of the circumscribed polygon cannot fall within the circle, nor the sides of the inscribed polygon without it, it follows *that the perimeters of the polygons will unite on the circumference of the circle, and become equal to it.*

*Cor. 3.* When the number of sides of the inscribed polygon is indefinitely increased, and the polygon coincides with the circle, the line  $OI$ , drawn from the centre  $O$ , perpendicular to the side of the polygon, will become a radius of the circle, and any portion of the polygon, as  $ABCO$ , will become the sector  $OAKBC$ ; and the part of the perimeter  $AB + BC$ , will become the arc  $AKBC$ .

#### PROPOSITION IX. THEOREM.

*The area of a regular polygon is equal to its perimeter, multiplied by half the radius of the inscribed circle.*

Let there be the regular polygon  $GHIK$ , and  $ON$ ,  $OT$ , radii of the inscribed circle. The triangle  $GOH$  will be measured by  $GH \times \frac{1}{2}OT$ ; the triangle  $OHI$ , by  $HI \times \frac{1}{2}ON$ : but  $ON = OT$ ; hence the two triangles taken together will be measured by  $(GH + HI) \times \frac{1}{2}OT$ . And, by continuing the same operation for the other triangles, it will appear that the sum of them all, or the whole polygon, is measured by the sum of the bases  $GH$ ,  $HI$ , &c. or the perimeter of the polygon, multiplied into  $\frac{1}{2}OT$ , or half the radius of the inscribed circle.

*Scholium.* The radius  $OT$  of the inscribed circle is nothing else than the perpendicular let fall from the centre on one of the sides: it is sometimes named the *apothem* of the polygon.

## PROPOSITION X. THEOREM.

*The perimeters of two regular polygons, having the same number of sides, are to each other as the radii of the circumscribed circles, and also, as the radii of the inscribed circles; and their areas are to each other as the squares of those radii.*

Let  $AB$  be the side of the one polygon,  $O$  the centre, and consequently  $OA$  the radius of the circumscribed circle, and  $OD$ , perpendicular to  $AB$ , the radius of the inscribed circle; let  $ab$ , in like manner, be a side of the other polygon,  $o$  its centre,  $oa$  and  $od$  the radii of the circumscribed and the inscribed circles. The perimeters of

the two polygons are to each other as the sides  $AB$  and  $ab$  (Book IV. Prop. XXVII.): but the angles  $A$  and  $a$  are equal, being each half of the angle of the polygon; so also are the angles  $B$  and  $b$ ; hence the triangles  $ABO$ ,  $abo$  are similar, as are likewise the right angled triangles  $ADO$ ,  $ado$ ; hence  $AB : ab :: AO : ao :: DO : do$ ; hence the perimeters of the polygons are to each other as the radii  $AO$ ,  $ao$  of the circumscribed circles, and also, as the radii  $DO$ ,  $do$  of the inscribed circles.

The surfaces of these polygons are to each other as the squares of the homologous sides  $AB$ ,  $ab$ ; they are therefore likewise to each other as the squares of  $AO$ ,  $ao$ , the radii of the circumscribed circles, or as the squares of  $OD$ ,  $od$ , the radii of the inscribed circles.

## PROPOSITION XI. THEOREM.

*The circumferences of circles are to each other as their radii, and the areas are to each other as the squares of their radii.*

*Cor. 2.* Let the circumference of the circle whose diameter is unity, be denoted by  $\pi$ : then, because circumferences are to each other as their radii or diameters, we shall have the diameter 1 to its circumference  $\pi$ , as the diameter  $2CA$  is to the circumference whose radius is  $CA$ , that is,  $1 : \pi :: 2CA : \text{circ. } CA$ , therefore  $\text{circ. } CA = \pi \times 2CA$ . Multiply both terms by  $\frac{1}{2}CA$ ; we have  $\frac{1}{2}CA \times \text{circ. } CA = \pi \times CA^2$ , or  $\text{area } CA = \pi \times CA^2$ : hence the area of a circle is equal to the product of the square of its radius by the constant number  $\pi$ , which represents the circumference whose diameter is 1, or the ratio of the circumference to the diameter.

In like manner, the area of the circle, whose radius is  $OB$ , will be equal to  $\pi \times OB^2$ ; but  $\pi \times CA^2 : \pi \times OB^2 :: CA^2 : OB^2$ ; hence *the areas of circles are to each other as the squares of their radii*, which agrees with the preceding theorem.

*Scholium.* We have already observed, that the problem of the quadrature of the circle consists in finding a square equal in surface to a circle, the radius of which is known. Now it has just been proved, that a circle is equivalent to the rectangle contained by its circumference and half its radius; and this rectangle may be changed into a square, by finding a mean proportional between its length and its breadth (Book IV. Prob. III.). To square the circle, therefore, is to find the circumference when the radius is given; and for effecting this, it is enough to know the ratio of the circumference to its radius, or its diameter.

Hitherto the ratio in question has never been determined except approximatively; but the approximation has been carried so far, that a knowledge of the exact ratio would afford no real advantage whatever beyond that of the approximate ratio. Accordingly, this problem, which engaged geometers so deeply, when their methods of approximation were less perfect, is now degraded to the rank of those idle questions, with which no one possessing the slightest tincture of geometrical science will occupy any portion of his time.

*Archimedes* showed that the ratio of the circumference to the diameter is included between  $3\frac{1}{7}$  and  $3\frac{1}{7}\frac{1}{11}$ ; hence  $3\frac{1}{7}$  or  $\frac{22}{7}$  affords at once a pretty accurate approximation to the number above designated by  $\pi$ ; and the simplicity of this first approximation has brought it into very general use. *Metius*, for the same number, found the much more accurate value  $3\frac{5}{113}$ . At last the value of  $\pi$ , developed to a certain order of decimals, was found by other calculators to be 3.1415926535897932, &c.:

and some have had patience enough to continue these decimals to the hundred and twenty-seventh, or even to the hundred and fortieth place. Such an approximation is evidently equivalent to perfect correctness: the root of an imperfect power is in no case more accurately known.

The following problem will exhibit one of the simplest elementary methods of obtaining those approximations.

PROPOSITION XIII. PROBLEM.

*The surface of a regular inscribed polygon, and that of a similar polygon circumscribed, being given; to find the surfaces of the regular inscribed and circumscribed polygons having double the number of sides.*

Let  $AB$  be a side of the given inscribed polygon;  $EF$ , parallel to  $AB$ , a side of the circumscribed polygon;  $C$  the centre of the circle. If the chord  $AM$  and the tangents  $AP$ ,  $BQ$ , be drawn,  $AM$  will be a side of the inscribed polygon, having twice the number of sides; and  $AP + PM = 2PM$  or  $PQ$ , will be a side of the similar circumscribed polygon (Prop. VI. Cor. 3.). Now, as the same

construction will take place at each of the angles equal to  $ACM$ , it will be sufficient to consider  $ACM$  by itself, the triangles connected with it being evidently to each other as the whole polygons of which they form part. Let  $A$ , then, be the surface of the inscribed polygon whose side is  $AB$ ,  $B$  that of the similar circumscribed polygon;  $A'$  the surface of the polygon whose side is  $AM$ ,  $B'$  that of the similar circumscribed polygon:  $A$  and  $B$  are given; we have to find  $A'$  and  $B'$ .

*First.* The triangles  $ACD$ ,  $ACM$ , having the common vertex  $A$ , are to each other as their bases  $CD$ ,  $CM$ ; they are likewise to each other as the polygons  $A$  and  $A'$ , of which they form part: hence  $A : A' :: CD : CM$ . Again, the triangles  $CAM$ ,  $CME$ , having the common vertex  $M$ , are to each other as their bases  $CA$ ,  $CE$ ; they are likewise to each other as the polygons  $A'$  and  $B$  of which they form part; hence  $A' : B :: CA : CE$ . But since  $AD$  and  $ME$  are parallel, we have  $CD : CM :: CA : CE$ ; hence  $A : A' :: A' : B$ ; hence the polygon  $A'$ , one of those required, is a mean proportional between the two given polygons  $A$  and  $B$  and consequently  $A' = \sqrt{A \times B}$ .

*Secondly.* The altitude CM being common, the triangle CPM is to the triangle CPE as PM is to PE; but since CP bisects the angle MCE, we have  $PM : PE :: CM : CE$  (Book IV. Prop. XVII.)  $:: CD : CA :: A : A'$ ; hence  $CPM : CPE :: A : A'$ ; and consequently  $CPM : CPM + CPE$ , or  $CME :: A : A + A'$ . But CMA, or  $2CMP$ , and CME are to each other as the polygons  $B'$

and B, of which they form part: hence  $B' : B :: 2A : A + A'$ . Now  $A'$  has been already determined; this new proportion will serve for determining  $B'$ , and give us  $B' = \frac{2A \cdot B}{A + A'}$ ; and thus by means of the polygons A and B it is easy to find the polygons  $A'$  and  $B'$ , which shall have double the number of sides.

#### PROPOSITION XIV. PROBLEM.

*To find the approximate ratio of the circumference to the diameter.*

Let the radius of the circle be 1; the side of the inscribed square will be  $\sqrt{2}$  (Prop. III. Sch.), that of the circumscribed square will be equal to the diameter 2; hence the surface of the inscribed square is 2, and that of the circumscribed square is 4. Let us therefore put  $A=2$ , and  $B=4$ ; by the last proposition we shall find the inscribed octagon  $A' = \sqrt{8} = 2.8284271$ ,

and the circumscribed octagon  $B' = \frac{16}{2 + \sqrt{8}} = 3.3137085$ . The inscribed and the circumscribed octagons being thus determined, we shall easily, by means of them, determine the polygons having twice the number of sides. We have only in this case to put  $A=2.8284271$ ,  $B=3.3137085$ ; we shall find  $A' =$

$\sqrt{A \cdot B} = 3.0614674$ , and  $B' = \frac{2A \cdot B}{A + A'} = 3.1825979$ . These polygons of 16 sides will in their turn enable us to find the polygons of 32; and the process may be continued, till there remains no longer any difference between the inscribed and the circumscribed polygon, at least so far as that place of decimals where the computation stops, and so far as the seventh place, in this example. Being arrived at this point, we shall infer

that the last result expresses the area of the circle, which, since it must always lie between the inscribed and the circumscribed polygon, and since those polygons agree as far as a certain place of decimals, must also agree with both as far as the same place.

We have subjoined the computation of those polygons, carried on till they agree as far as the seventh place of decimals.

| Number of sides | Inscribed polygh. | Circumscribed polygon. |
|-----------------|-------------------|------------------------|
| 4 . . . . .     | 2.0000000         | 4.0000000              |
| 8 . . . . .     | 2.8284271         | 3.3137085              |
| 16 . . . . .    | 3.0614674         | 3.1825979              |
| 32 . . . . .    | 3.1214451         | 3.1517249              |
| 64 . . . . .    | 3.1365485         | 3.1441184              |
| 128 . . . . .   | 3.1403311         | 3.1422236              |
| 256 . . . . .   | 3.1412772         | 3.1417504              |
| 512 . . . . .   | 3.1415138         | 3.1416321              |
| 1024 . . . . .  | 3.1415729         | 3.1416025              |
| 2048 . . . . .  | 3.1415877         | 3.1415951              |
| 4096 . . . . .  | 3.1415914         | 3.1415933              |
| 8192 . . . . .  | 3.1415923         | 3.1415928              |
| 16384 . . . . . | 3.1415925         | 3.1415927              |
| 32768 . . . . . | 3.1415926         | 3.1415926              |

The area of the circle, we infer therefore, is equal to 3.1415926. Some doubt may exist perhaps about the last decimal figure, owing to errors proceeding from the parts omitted; but the calculation has been carried on with an additional figure, that the final result here given might be absolutely correct even to the last decimal place.

Since the area of the circle is equal to half the circumference multiplied by the radius, the half circumference must be 3.1415926, when the radius is 1; or the whole circumference must be 3.1415926, when the diameter is 1: hence the ratio of the circumference to the diameter, formerly expressed by  $\pi$ , is equal to 3.1415926. The number 3.1416 is the one generally used

## BOOK VI.

## PLANES AND SOLID ANGLES.

*Definitions.*

1. A straight line is *perpendicular to a plane*, when it is perpendicular to all the straight lines which pass through its *foot* in the plane. Conversely, the plane is perpendicular to the line.

The *foot* of the perpendicular is the point in which the perpendicular line meets the plane.

2. A line is *parallel to a plane*, when it cannot meet that plane, to whatever distance both be produced. Conversely, the plane is parallel to the line.

3. Two *planes* are *parallel* to each other, when they cannot meet, to whatever distance both be produced.

4. The *angle* or *mutual inclination of two planes* is the quantity, greater or less, by which they separate from each other; this angle is measured by the angle contained between two lines, one in each plane, and both perpendicular to the common intersection at the same point.

This angle may be acute, obtuse, or a right angle.

If it is a right angle, the two *planes* are perpendicular to each other.

5. A *solid angle* is the angular space included between several planes which meet at the same point.

Thus, the solid angle *S*, is formed by the union of the planes *ASB*, *BSC*, *CSD*, *DSA*.

Three planes at least, are requisite to form a solid angle.

## PROPOSITION I. THEOREM.

*A straight line cannot be partly in a plane, and partly out of it.*

For, by the definition of a plane, when a straight line has two points common with a plane, it lies wholly in that plane.

*Scholium.* To discover whether a surface is plane, it is necessary to apply a straight line in different ways to that surface, and ascertain if it touches the surface throughout its whole extent.

## PROPOSITION II. THEOREM.

*Two straight lines, which intersect each other, lie in the same plane, and determine its position.*

Let  $AB, AC$ , be two straight lines which intersect each other in  $A$ ; a plane may be conceived in which the straight line  $AB$  is found; if this plane be turned round  $AB$ , until it pass through the point  $C$ , then the line  $AC$ , which has two of its points  $A$  and  $C$ , in this plane, lies wholly in it; hence the position of the plane is determined by the single condition of containing the two straight lines  $AB, AC$ .

*Cor. 1.* A triangle  $ABC$ , or three points  $A, B, C$ , not in a straight line, determine the position of a plane.

*Cor. 2.* Hence also two parallels  $AB, CD$ , determine the position of a plane; for, drawing the secant  $EF$ , the plane of the two straight lines  $AE, EF$ , is that of the parallels  $AB, CD$ .

## PROPOSITION III. THEOREM.

*If two planes cut each other, their common intersection will be a straight line.*

Let the two planes AB, CD, cut each other. Draw the straight line EF, joining any two points E and F in the common section of the two planes. This line will lie wholly in the plane AB, and also wholly in the plane CD (Book I. Def. 6.): therefore it will be in both planes at once, and consequently is their common intersection.

#### PROPOSITION IV. THEOREM.

*If a straight line be perpendicular to two straight lines at their point of intersection, it will be perpendicular to the plane of those lines.*

Let MN be the plane of the two lines BB, CC, and let AP be perpendicular to them at their point of intersection P; then will AP be perpendicular to every line of the plane passing through P, and consequently to the plane itself (Def. 1.).

Through P, draw in the plane MN, any straight line as PQ, and through any point of this line, as Q, draw BQC, so that BQ shall be equal to QC (Book IV. Prob. V.); draw AB, AQ, AC.

The base BC being divided into two equal parts at the point Q, the triangle BPC will give (Book IV. Prop. XIV.),

$$PC^2 + PB^2 = 2PQ^2 + 2QC^2.$$

The triangle BAC will in like manner give,

$$AC^2 + AB^2 = 2AQ^2 + 2QC^2.$$

Taking the first equation from the second, and observing that the triangles APC, APB, which are both right angled at P, give

$$AC^2 - PC^2 = AP^2, \text{ and } AB^2 - PB^2 = AP^2;$$

we shall have

$$AP^2 + AP^2 = 2AQ^2 - 2PQ^2.$$

Therefore, by taking the halves of both, we have

$$AP^2 = AQ^2 - PQ^2, \text{ or } AQ^2 = AP^2 + PQ^2;$$

hence the triangle APQ is right angled at P; hence AP is perpendicular to PQ.

*Scholium.* Thus it is evident, not only that a straight line may be perpendicular to all the straight lines which pass through its foot in a plane, but that it always must be so, whenever it is perpendicular to two straight lines drawn in the plane; which proves the first Definition to be accurate.

*Cor. 1.* The perpendicular AP is shorter than any oblique line AQ; therefore it measures the true distance from the point A to the plane MN.

*Cor. 2.* At a given point P on a plane, it is impossible to erect more than one perpendicular to that plane; for if there could be two perpendiculars at the same point P, draw through these two perpendiculars a plane, whose intersection with the plane MN is PQ; then these two perpendiculars would be perpendicular to the line PQ, at the same point, and in the same plane, which is impossible (Book I. Prop. XIV. Sch.).

It is also impossible to let fall from a given point out of a plane two perpendiculars to that plane; for let AP, AQ, be these two perpendiculars, then the triangle APQ would have two right angles APQ, AQP, which is impossible.

#### PROPOSITION V. THEOREM.

*If from a point without a plane, a perpendicular be drawn to the plane, and oblique lines be drawn to different points,*

- 1st. Any two oblique lines equally distant from the perpendicular will be equal.*
- 2d. Of any two oblique lines unequally distant from the perpendicular, the more distant will be the longer.*

Let AP be perpendicular to the plane MN; AB, AC, AD, oblique lines equally distant from the perpendicular, and AE a line more remote: then will  $AB=AC=AD$ ; and AE will be greater than AD.

For, the angles APB, APC, APD, being right angles, if we suppose the distances PB, PC, PD, to be equal to each other, the triangles APB, APC, APD, will have in each an equal angle contained by two equal sides: therefore they will be equal; hence the hypotenuses, or the oblique lines AB, AC, AD, will be equal to each other. In like

manner, if the distance  $PE$  is greater than  $PD$  or its equal  $PB$ , the oblique-line  $AE$  will evidently be greater than  $AB$ , or its equal  $AD$ .

*Cor.* All the equal oblique lines,  $AB$ ,  $AC$ ,  $AD$ , &c. terminate in the circumference  $BCD$ , described from  $P$  the foot of the perpendicular as a centre; therefore a point  $A$  being given out of a plane, the point  $P$  at which the perpendicular let fall from  $A$  would meet that plane, may be found by marking upon that plane three points  $B$ ,  $C$ ,  $D$ , equally distant from the point  $A$ , and then finding the centre of the circle which passes through these points; this centre will be  $P$ , the point sought.

*Scholium.* The angle  $ABP$  is called the *inclination of the oblique line  $AB$  to the plane  $MN$* ; which inclination is evidently equal with respect to all such lines  $AB$ ,  $AC$ ,  $AD$ , as are equally distant from the perpendicular; for all the triangles  $ABP$ ,  $ACP$ ,  $ADP$ , &c. are equal to each other.

#### PROPOSITION VI. THEOREM.

*If from a point without a plane, a perpendicular be let fall on the plane, and from the foot of the perpendicular a perpendicular be drawn to any line of the plane, and from the point of intersection a line be drawn to the first point, this latter line will be perpendicular to the line of the plane.*

Let  $AP$  be perpendicular to the plane  $NM$ , and  $PD$  perpendicular to  $BC$ ; then will  $AD$  be also perpendicular to  $BC$ .

Take  $DB=DC$ , and draw  $PB$ ,  $PC$ ,  $AB$ ,  $AC$ . Since  $DB=DC$ , the oblique line  $PB=PC$ : and with regard to the perpendicular  $AP$ , since  $PB=PC$ , the oblique line  $AB=AC$  (Prop. V. Cor.); therefore the line  $AD$  has two of its points  $A$  and  $D$  equally distant from the extremities  $B$  and  $C$ ; therefore  $AD$  is a perpendicular to  $BC$ , at its middle point  $D$  (Book I. Prop. XVI. Cor.).

*Cor.* It is evident likewise, that  $BC$  is perpendicular to the plane  $APD$ , since  $BC$  is at once perpendicular to the two straight lines  $AD$ ,  $PD$ .

*Scholium.* The two lines  $AE$ ,  $BC$ , afford an instance of two lines which do not meet, because they are not situated in the same plane. The shortest distance between these lines is the straight line  $PD$ , which is at once perpendicular to the line  $AP$  and to the line  $BC$ . The distance  $PD$  is the shortest distance between them, because if we join any other two points, such as  $A$  and  $B$ , we shall have  $AB > AD$ ,  $AD > PD$ ; therefore  $AB > PD$ .

The two lines  $AE$ ,  $CB$ , though not situated in the same plane, are conceived as forming a right angle with each other, because  $AE$  and the line drawn through one of its points parallel to  $BC$  would make with each other a right angle. In the same manner, the line  $AB$  and the line  $PD$ , which represent any two straight lines not situated in the same plane, are supposed to form with each other the same angle, which would be formed by  $AB$  and a straight line parallel to  $PD$  drawn through one of the points of  $AB$ .

#### PROPOSITION VII. THEOREM.

*If one of two parallel lines be perpendicular to a plane, the other will also be perpendicular to the same plane.*

Let the lines  $ED$ ,  $AP$ , be parallel; if  $AP$  is perpendicular to the plane  $NM$ , then will  $ED$  be also perpendicular to it.

Through the parallels  $AP$ ,  $DE$ , pass a plane; its intersection with the plane  $MN$  will be  $PD$ ; in the plane  $MN$  draw  $BC$  perpendicular to  $PD$ , and draw  $AD$ .

By the Corollary of the preceding Theorem,  $BC$  is perpendicular to the plane  $APDE$ ; therefore the angle  $BDE$  is a right angle; but the angle  $EDP$  is also a right angle, since  $AP$  is perpendicular to  $PD$ , and  $DE$  parallel to  $AP$  (Book I. Prop. XX. Cor. 1.); therefore the line  $DE$  is perpendicular to the two straight lines  $DP$ ,  $DB$ ; consequently it is perpendicular to their plane  $MN$  (Prop. IV.)

*Cor. 1.* Conversely, if the straight lines  $AP$ ,  $DE$ , are perpendicular to the same plane  $MN$ , they will be parallel; for if they be not so, draw through the point  $D$ , a line parallel to  $AP$ , this parallel will be perpendicular to the plane  $MN$ ; therefore through the same point  $D$  more than one perpendicular might be erected to the same plane, which is impossible (Prop. IV. Cor. 2.).

*Cor. 2.* Two lines  $A$  and  $B$ , parallel to a third  $C$ , are parallel to each other; for, conceive a plane perpendicular to the line  $C$ ; the lines  $A$  and  $B$ , being parallel to  $C$ , will be perpendicular to the same plane; therefore, by the preceding Corollary, they will be parallel to each other.

The three lines are supposed not to be in the same plane; otherwise the proposition would be already known (Book I. Prop. XXII.).

#### PROPOSITION VIII. THEOREM.

*If a straight line is parallel to a straight line drawn in a plane, it will be parallel to that plane.*

Let  $AB$  be parallel to  $CD$  of the plane  $NM$ ; then will it be parallel to the plane  $NM$ .

For, if the line  $AB$ , which lies in the plane  $ABDC$ , could meet the plane  $MN$ , this could only be in some point of the line  $CD$ , the common intersection of the two planes: but  $AB$  cannot meet  $CD$ , since they are parallel; hence it will not meet the plane  $MN$ ; hence it is parallel to that plane (Def. 2.).

#### PROPOSITION IX. THEOREM.

*Two planes which are perpendicular to the same straight line, are parallel to each other.*

Let the planes  $NM$ ,  $QP$ , be perpendicular to the line  $AB$ , then will they be parallel.

For, if they can meet any where, let  $O$  be one of their common points, and draw  $OA$ ,  $OB$ ; the line  $AB$  which is perpendicular to the plane  $MN$ , is perpendicular to the straight line  $OA$  drawn through its foot in that plane; for the same reason  $AB$  is perpendicular to  $BO$ ; therefore  $OA$  and  $OB$  are two perpendiculars let fall from the same point  $O$ , upon the same straight line; which is impossible (Book I. Prop. XIV.); therefore the planes  $MN$ ,  $PQ$ , cannot meet each other; consequently they are parallel.

#### PROPOSITION X. THEOREM.

*If a plane cut two parallel planes, the lines of intersection will be parallel.*

Let the parallel planes  $NM$ ,  $QP$ , be intersected by the plane  $EH$ ; then will the lines of intersection  $EF$ ,  $GH$ , be parallel.

For, if the lines  $EF$ ,  $GH$ , lying in the same plane, were not parallel, they would meet each other when produced; therefore, the planes  $MN$ ,  $PQ$ , in which those lines lie, would also meet; and hence the planes would not be parallel.

#### PROPOSITION XI. THEOREM.

*If two planes are parallel, a straight line which is perpendicular to one, is also perpendicular to the other.*

Let  $MN$ ,  $PQ$ , be two parallel planes, and let  $AB$  be perpendicular to  $NM$ ; then will it also be perpendicular to  $QP$ .

Having drawn any line  $BC$  in the plane  $PQ$ , through the lines  $AB$  and  $BC$ , draw a plane  $ABC$ , intersecting the plane  $MN$  in  $AD$ ; the intersection  $AD$  will be parallel to  $BC$  (Prop. X.); but the line  $AB$ , being perpendicular to the plane  $MN$ , is perpendicular to the straight line  $AD$ ; therefore also, to its parallel  $BC$  (Book I. Prop. XX. Cor. 1.): hence the line  $AB$  being perpendicular to any line  $BC$ , drawn through its foot in the plane  $PQ$ , is consequently perpendicular to that plane (Def. 1.).

### PROPOSITION XII. THEOREM.

*The parallels comprehended between two parallel planes are equal.*

Let  $MN$ ,  $PQ$ , be two parallel planes, and  $FH$ ,  $GE$ , two parallel lines: then will  $EG = FH$ .

For, through the parallels  $EG$ ,  $FH$ , draw the plane  $EGHF$ , intersecting the parallel planes in  $EF$  and  $GH$ . The intersections  $EF$ ,  $GH$ , are parallel to each other (Prop. X.); so likewise are  $EG$ ,  $FH$ ; therefore the figure  $EGHF$  is a parallelogram; consequently,  $EG = FH$ .

*Cor.* Hence it follows, that *two parallel planes are every where equidistant*: for, suppose  $EG$  were perpendicular to the plane  $PQ$ ; the parallel  $FH$  would also be perpendicular to it (Prop. VII.), and the two parallels would likewise be perpendicular to the plane  $MN$  (Prop. XI.); and being parallel, they will be equal, as shown by the Proposition.

## PROPOSITION XIII. THEOREM.

*If two angles, not situated in the same plane, have their sides parallel and lying in the same direction, those angles will be equal and their planes will be parallel.*

Let the angles be  $CAE$  and  $DBF$ .

Make  $AC=BD$ ,  $AE=BF$ ; and draw  $CE$ ,  $DF$ ,  $AB$ ,  $CD$ ,  $EF$ . Since  $AC$  is equal and parallel to  $BD$ , the figure  $ABDC$  is a parallelogram; therefore  $CD$  is equal and parallel to  $AB$ . For a similar reason,  $EF$  is equal and parallel to  $AB$ ; hence also  $CD$  is equal and parallel to  $EF$ ; hence the figure  $CEFD$  is a parallelogram, and the side  $CE$  is equal and parallel to  $DF$ ; therefore the triangles  $CAE$ ,  $DBF$ , have their corresponding sides equal; therefore the angle  $CAE=DBF$ .

Again, the plane  $ACE$  is parallel to the plane  $BDF$ . For suppose the plane drawn through the point  $A$ , parallel to  $BDF$ , were to meet the lines  $CD$ ,  $EF$ , in points different from  $C$  and  $E$ , for instance in  $G$  and  $H$ ; then, the three lines  $AB$ ,  $GD$ ,  $FH$ , would be equal (Prop. XII.): but the lines  $AB$ ,  $CD$ ,  $EF$ , are already known to be equal; hence  $CD=GD$ , and  $FH=EF$ , which is absurd; hence the plane  $ACE$  is parallel to  $BDF$ .

*Cor.* If two parallel planes  $MN$ ,  $PQ$  are met by two other planes  $CABD$ ,  $EABF$ , the angles  $CAE$ ,  $DBF$ , formed by the intersections of the parallel planes will be equal; for, the intersection  $AC$  is parallel to  $BD$ , and  $AE$  to  $BF$  (Prop. X.); therefore the angle  $CAE=DBF$ .

## PROPOSITION XIV. THEOREM.

*If three straight lines, not situated in the same plane, are equal and parallel, the opposite triangles formed by joining the extremities of these lines will be equal, and their planes will be parallel.*

Let  $AB$ ,  $CD$ ,  $EF$ , be the lines.

Since  $AB$  is equal and parallel to  $CD$ , the figure  $ABDC$  is a parallelogram; hence the side  $AC$  is equal and parallel to  $BD$ . For a like reason the sides  $AE$ ,  $BF$ , are equal and parallel, as also  $CE$ ,  $DF$ ; therefore the two triangles  $ACE$ ,  $BDF$ , are equal; hence, by the last Proposition, their planes are parallel.

#### PROPOSITION XV. THEOREM.

*If two straight lines be cut by three parallel planes, they will be divided proportionally.*

Suppose the line  $AB$  to meet the parallel planes  $MN$ ,  $PQ$ ,  $RS$ , at the points  $A$ ,  $E$ ,  $B$ ; and the line  $CD$  to meet the same planes at the points  $C$ ,  $F$ ,  $D$ : we are now to show that

$$AE : EB :: CF : FD.$$

Draw  $AD$  meeting the plane  $PQ$  in  $G$ , and draw  $AC$ ,  $EG$ ,  $GF$ ,  $BD$ ; the intersections  $EG$ ,  $GF$ ,  $BD$ , of the parallel planes  $PQ$ ,  $RS$ , by the plane  $ABD$ , are parallel (Prop. X.); therefore

$$AE : EB :: AG : GD;$$

in like manner, the intersections  $AC$ ,  $GF$ , being parallel,

$$AG : GD :: CF : FD;$$

the ratio  $AG : GD$  is the same in both; hence

$$AE : EB :: CF : FD.$$

#### PROPOSITION XVI. THEOREM.

*If a line is perpendicular to a plane, every plane passed through the perpendicular, will also be perpendicular to the plane.*

Let  $AP$  be perpendicular to the plane  $NM$ ; then will every plane passing through  $AP$  be perpendicular to  $NM$ .

Let  $BC$  be the intersection of the planes  $AB, MN$ ; in the plane  $MN$ , draw  $DE$  perpendicular to  $BP$ : then the line  $AP$ , being perpendicular to the plane  $MN$ , will be perpendicular to each of the two straight lines  $BC, DE$ ; but the angle  $APD$ , formed by the two perpendiculars  $PA, PD$ , to the common intersection  $BP$ , measures the angle of the two planes  $AB, MN$  (Def. 4.); therefore, since that angle is a right angle, the two planes are perpendicular to each other.

*Scholium.* When three straight lines, such as  $AP, BP, DP$ , are perpendicular to each other, each of those lines is perpendicular to the plane of the other two, and the three planes are perpendicular to each other.

#### PROPOSITION XVII. THEOREM.

*If two planes are perpendicular to each other, a line drawn in one of them perpendicular to their common intersection, will be perpendicular to the other plane.*

Let the plane  $AB$  be perpendicular to  $NM$ ; then if the line  $AP$  be perpendicular to the intersection  $BC$ , it will also be perpendicular to the plane  $NM$ .

For, in the plane  $MN$  draw  $PD$  perpendicular to  $PB$ ; then, because the planes are perpendicular, the angle  $APD$  is a right angle; therefore, the line  $AP$  is perpendicular to the two straight lines  $PB, PD$ ; therefore it is perpendicular to their plane  $MN$  (Prop. IV.).

*Cor.* If the plane  $AB$  is perpendicular to the plane  $MN$ , and if at a point  $P$  of the common intersection we erect a perpendicular to the plane  $MN$ , that perpendicular will be in the plane  $AB$ : for, if not, then, in the plane  $AB$  we might draw  $AP$  per-

pendicular to  $PB$  the common intersection, and this  $AP$ , at the same time, would be perpendicular to the plane  $MN$ ; therefore at the same point  $P$  there would be two perpendiculars to the plane  $MN$ , which is impossible (Prop. IV. Cor. 2.).

PROPOSITION XVIII. THEOREM.

*If two planes are perpendicular to a third plane, their common intersection will also be perpendicular to the third plane.*

Let the planes  $AB, AD$ , be perpendicular to  $NM$ ; then will their intersection  $AP$  be perpendicular to  $NM$ .

For, at the point  $P$ , erect a perpendicular to the plane  $MN$ ; that perpendicular must be at once in the plane  $AB$  and in the plane  $AD$  (Prop. XVII. Cor.); therefore it is their common intersection  $AP$ .

PROPOSITION XIX. THEOREM.

*If a solid angle is formed by three plane angles, the sum of any two of these angles will be greater than the third.*

The proposition requires demonstration only when the plane angle, which is compared to the sum of the other two, is greater than either of them. Therefore suppose the solid angle  $S$  to be formed by three plane angles  $ASB, ASC, BSC$ , whereof the angle  $ASB$  is the greatest; we are to show that  $ASB < ASC + BSC$ .

In the plane  $ASB$  make the angle  $BSD = BSC$ , draw the straight line  $ADB$  at pleasure; and having taken  $SC = SD$ , draw  $AC, BC$ .

The two sides  $BS, SD$ , are equal to the two  $BS, SC$ ; the angle  $BSD = BSC$ ; therefore the triangles  $BSD, BSC$ , are equal; therefore  $BD = BC$ . But  $AB < AC + BC$ ; taking  $BD$  from the one side, and from the other its equal  $BC$ , there re

mains  $AD < AC$ . The two sides  $AS, SD$ , are equal to the two  $AS, SC$ ; the third side  $AD$  is less than the third side  $AC$ ; therefore the angle  $ASD < ASC$  (Book I. Prop. IX. Sch.). Adding  $BSD = BSC$ , we shall have  $ASD + BSD$  or  $ASB < ASC + BSC$ .

PROPOSITION XX. THEOREM.

*The sum of the plane angles which form a solid angle is always less than four right angles.*

Cut the solid angle  $S$  by any plane  $ABCDE$ ; from  $O$ , a point in that plane, draw to the several angles the straight lines  $AO, OB, OC, OD, OE$ .

The sum of the angles of the triangles  $ASB, BSC$ , &c. formed about the vertex  $S$ , is equal to the sum of the angles of an equal number of triangles  $AOB, BOC$ , &c. formed about the point  $O$ . But at the point  $B$  the sum of the angles  $ABO, OBC$ , equal to  $ABC$ , is less than the sum of the angles  $ABS, SBC$  (Prop. XIX.); in the same manner at the point  $C$  we have  $BCO + OCD < BCS + SCD$ ; and so with all the angles of the polygon  $ABCDE$ : whence it follows, that the sum of all the angles at the bases of the triangles whose vertex is in  $O$ , is less than the sum of the angles at the bases of the triangles whose vertex is in  $S$ ; hence to make up the deficiency, the sum of the angles formed about the point  $O$ , is greater than the sum of the angles formed about the point  $S$ . But the sum of the angles about the point  $O$  is equal to four right angles (Book I. Prop. IV. Sch.); therefore the sum of the plane angles, which form the solid angle  $S$ , is less than four right angles.

*Scholium.* This demonstration is founded on the supposition that the solid angle is convex, or that the plane of no one surface produced can ever meet the solid angle; if it were otherwise, the sum of the plane angles would no longer be limited, and might be of any magnitude.

PROPOSITION XXI. THEOREM.

*If two solid angles are contained by three plane angles which are equal to each other, each to each, the planes of the equal angles will be equally inclined to each other*

Let the angle  $ASC = DTF$ , the angle  $ASB = DTE$ , and the angle  $BSC = ETF$ ; then will the inclination of the planes  $ASC$ ,  $ASB$ , be equal to that of the planes  $DTF$ ,  $DTE$ .

Having taken  $SB$  at pleasure, draw  $BO$  perpendicular to the plane  $ASC$ ; from the point  $O$ , at which the perpendicular meets the plane, draw  $OA$ ,  $OC$  perpendicular to  $SA$ ,  $SC$ ; draw  $AB$ ,  $BC$ ; next take  $TE = SB$ ; draw  $EP$  perpendicular to the plane  $DTF$ ; from the point  $P$  draw  $PD$ ,  $PF$ , perpendicular respectively to  $TD$ ,  $TF$ ; lastly, draw  $DE$ ,  $EF$ .

The triangle  $SAB$  is right angled at  $A$ , and the triangle  $TDE$  at  $D$  (Prop. VI.): and since the angle  $ASB = DTE$  we have  $SBA = TED$ . Likewise  $SB = TE$ ; therefore the triangle  $SAB$  is equal to the triangle  $TDE$ ; therefore  $SA = TD$ , and  $AB = DE$ . In like manner, it may be shown, that  $SC = TF$ , and  $BC = EF$ . That granted, the quadrilateral  $SAOC$  is equal to the quadrilateral  $TDPE$ : for, place the angle  $ASC$  upon its equal  $DTF$ ; because  $SA = TD$ , and  $SC = TF$ , the point  $A$  will fall on  $D$ , and the point  $C$  on  $F$ ; and at the same time,  $AO$ , which is perpendicular to  $SA$ , will fall on  $PD$  which is perpendicular to  $TD$ , and in like manner  $OC$  on  $PF$ ; wherefore the point  $O$  will fall on the point  $P$ , and  $AO$  will be equal to  $DP$ . But the triangles  $AOB$ ,  $DPE$ , are right angled at  $O$  and  $P$ ; the hypotenuse  $AB = DE$ , and the side  $AO = DP$ : hence those triangles are equal (Book I. Prop. XVII.); and consequently, the angle  $OAB = PDE$ . The angle  $OAB$  is the inclination of the two planes  $ASB$ ,  $ASC$ ; and the angle  $PDE$  is that of the two planes  $DTE$ ,  $DTF$ ; hence those two inclinations are equal to each other.

It must, however, be observed, that the angle  $A$  of the right angled triangle  $AOB$  is properly the inclination of the two planes  $ASB$ ,  $ASC$ , only when the perpendicular  $BO$  falls on the same side of  $SA$ , with  $SC$ ; for if it fell on the other side, the angle of the two planes would be obtuse, and the obtuse angle together with the angle  $A$  of the triangle  $AOB$  would make two right angles. But in the same case, the angle of the two planes  $TDE$ ,  $TDF$ , would also be obtuse, and the obtuse angle together with the angle  $D$  of the triangle  $DPE$ , would make two right angles; and the angle  $A$  being thus always equal to the angle at  $D$ , it would follow in the same manner that the inclination of the two planes  $ASB$ ,  $ASC$ , must be equal to that of the two planes  $TDE$ ,  $TDF$ .

*Scholium.* If two solid angles are contained by three plane

angles, respectively equal to each other, and if at the same time the equal or homologous angles are *disposed in the same manner* in the two solid angles, these angles will be equal, and they will coincide when applied the one to the other. We have already seen that the quadrilateral SAOC may be placed upon its equal TDPF; thus placing SA upon TD, SC falls upon TF, and the point O upon the point P. But because the triangles AOB, DPE, are equal, OB, perpendicular to the plane ASC, is equal to PE, perpendicular to the plane TDF; besides, those perpendiculars lie in the same direction; therefore, the point B will fall upon the point E, the line SB upon TE, and the two solid angles will wholly coincide.

This coincidence, however, takes place only when we suppose that the equal plane angles are *arranged in the same manner* in the two solid angles; for if they were *arranged in an inverse order*, or, what is the same, if the perpendiculars OB, PE, instead of lying in the same direction with regard to the planes ASC, DTF, lay in opposite directions, then it would be impossible to make these solid angles coincide with one another. It would not, however, on this account, be less true, as our Theorem states, that the planes containing the equal angles must still be equally inclined to each other; so that the two solid angles would be equal in all their constituent parts, without, however, admitting of superposition. This sort of equality, which is not absolute, or such as admits of superposition, deserves to be distinguished by a particular name: we shall call it *equality by symmetry*.

Thus those two solid angles, which are formed by three plane angles respectively equal to each other, but disposed in an inverse order, will be called *angles equal by symmetry*, or simply *symmetrical angles*.

The same remark is applicable to solid angles, which are formed by more than three plane angles: thus a solid angle, formed by the plane angles A, B, C, D, E, and another solid angle, formed by the same angles in an inverse order A, E, D, C, B, may be such that the planes which contain the equal angles are equally inclined to each other. Those two solid angles, are likewise equal, without being capable of superposition, and are called *solid angles equal by symmetry*, or *symmetrical solid angles*.

Among plane figures, equality by symmetry does not properly exist, all figures which might take this name being absolutely equal, or equal by superposition; the reason of which is, that a plane figure may be inverted, and the upper part taken indiscriminately for the under. This is not the case with solids; in which the third dimension may be taken in two different directions.

## BOOK VII.

## POLYEDRONS.

*Definitions.*

1. THE name *solid polyedron*, or simple *polyedron*, is given to every solid terminated by planes or plane faces; which planes, it is evident, will themselves be terminated by straight lines.

2. The common intersection of two adjacent faces of a polyedron is called the *side*, or *edge* of the polyedron.

3. The *prism* is a solid bounded by several parallelograms, which are terminated at both ends by equal and parallel polygons.

To construct this solid, let  $ABCDE$  be any polygon; then if in a plane parallel to  $ABCDE$ , the lines  $FG$ ,  $GH$ ,  $HI$ , &c. be drawn equal and parallel to the sides  $AB$ ,  $BC$ ,  $CD$ , &c. thus forming the polygon  $FGHIK$  equal to  $ABCDE$ ; if in the next place, the vertices of the angles in the one plane be joined with the homologous vertices in the other, by straight lines,  $AF$ ,  $BG$ ,  $CH$ , &c. the faces  $ABGF$ ,  $BCHG$ , &c. will be parallelograms, and  $ABCDE-K$ , the solid so formed, will be a prism.

4. The equal and parallel polygons  $ABCDE$ ,  $FGHIK$ . are called the *bases of the prism*; the parallelograms taken together constitute the *lateral* or *convex surface of the prism*; the equal straight lines  $AF$ ,  $BG$ ,  $CH$ , &c. are called the *sides*, or *edges of the prism*.

5. The *altitude of a prism* is the distance between its two bases, or the perpendicular drawn from a point in the upper base to the plane of the lower base.

6. A *prism* is *right*, when the sides AF, BG, CH, &c. are perpendicular to the planes of the bases; and then each of them is equal to the altitude of the prism. In every other case the prism is *oblique*, and the altitude less than the side.

7. A *prism* is *triangular*, *quadrangular*, *pentagonal*, *hexagonal*, &c. when the base is a triangle, a quadrilateral, a pentagon, a hexagon, &c.

8. A prism whose base is a parallelogram, and which has all its faces parallelograms, is named a *parallelopipedon*.

The *parallelopipedon* is *rectangular* when all its faces are rectangles.

9. Among rectangular parallelopipedons, we distinguish the *cube*, or regular hexaedron, bounded by six equal squares.

10. A *pyramid* is a solid formed by several triangular planes proceeding from the same point S, and terminating in the different sides of the same polygon ABCDE.

The polygon ABCDE is called the base of the pyramid, the point S the vertex; and the triangles ASB, BSC, CSD, &c. form its *convex* or *lateral* surface.

11. If from the pyramid S-ABCDE, the pyramid S-abcde be cut off by a plane parallel to the base, the remaining solid ABCDE-d, is called a *truncated pyramid*, or the frustum of a pyramid.

12. The *altitude* of a pyramid is the perpendicular let fall from the vertex upon the plane of the base, produced if necessary.

13. A pyramid is *triangular*, *quadrangular*, &c. according as its base is a triangle, a quadrilateral, &c.

14. A pyramid is *regular*, when its base is a regular polygon, and when, at the same time, the perpendicular let fall from the vertex on the plane of the base passes through the centre of the base. That perpendicular is then called the *axis* of the pyramid.

15. Any line, as SF, drawn from the vertex S of a regular pyramid, perpendicular to either side of the polygon which forms its base, is called the *slant height* of the pyramid.

16. The *diagonal* of a polyedron is a straight line joining the vertices of two solid angles which are not adjacent to each other.

17. Two polyedrons are *similar* when they are contained by the same number of similar planes, similarly situated, and having like inclinations with each other.

PROPOSITION I. THEOREM.

*The convex surface of a right prism is equal to the perimeter of its base multiplied by its altitude.*

Let  $ABCDE-K$  be a right prism: then will its convex surface be equal to  $(AB + BC + CD + DE + EA) \times AF$ .

For, the convex surface is equal to the sum of all the rectangles  $AG, BH, CI, DK, EF$ , which compose it. Now, the altitudes  $AF, BG, CH, \&c.$  of the rectangles, are equal to the altitude of the prism. Hence, the sum of these rectangles, or the convex surface of the prism, is equal to  $(AB + BC + CD + DE + EA) \times AF$ ; that is, to the perimeter of the base of the prism multiplied by its altitude.

*Cor.* If two right prisms have the same altitude, their convex surfaces will be to each other as the perimeters of their bases.

PROPOSITION II. THEOREM.

*In every prism, the sections formed by parallel planes, are equal polygons.*

Let the prism  $AH$  be intersected by the parallel planes  $NP, SV$ ; then are the polygons  $NOPQR, STVXY$  equal.

For, the sides  $ST, NO$ , are parallel, being the intersections of two parallel planes with a third plane  $ABGF$ ; these same sides,  $ST, NO$ , are included between the parallels  $NS, OT$ , which are sides of the prism: hence  $NO$  is equal to  $ST$ . For like reasons, the sides  $OP, PQ, QR, \&c.$  of the section  $NOPQR$ , are equal to the sides  $TV, VX, XY, \&c.$  of the section  $STVXY$ , each to each. And since

the equal sides are at the same time parallel, it follows that the angles NOP, OPQ, &c. of the first section, are equal to the angles STV, TVX, &c. of the second, each to each (Book VI. Prop. XIII.). Hence the two sections NOPQR, STVXY, are equal polygons.

*Cor.* Every section in a prism, if drawn parallel to the base, is also equal to the base.

### PROPOSITION III. THEOREM.

*If a pyramid be cut by a plane parallel to its bas ;*

*1st. The edges and the altitude will be divided proportionally.*

*2d. The section will be a polygon similar to the base.*

Let the pyramid S-ABCDE, of which SO is the altitude, be cut by the plane *abcde*; then will  $Sa : SA :: So : SO$ , and the same for the other edges: and the polygon *abcde*, will be similar to the base ABCDE.

*First.* Since the planes ABC, *abc*, are parallel, their intersections AB, *ab*, by a third plane SAB will also be parallel (Book VI. Prop. X.); hence the triangles SAB, Sab are similar, and we have  $SA : Sa :: SB : Sb$ ; for a similar reason, we have  $SB : Sb :: SC : Sc$ ; and so on. Hence the edges SA, SB, SC, &c. are cut proportionally in *a*, *b*, *c*, &c. The altitude SO is likewise cut in the same proportion, at the point *o*; for BO and *bo* are parallel, therefore we have

$$SO : So :: SB : Sb.$$

*Secondly.* Since *ab* is parallel to AB, *bc* to BC, *cd* to CD, &c. the angle *abc* is equal to ABC, the angle *bcd* to BCD, and so on (Book VI. Prop. XIII.). Also, by reason of the similar triangles SAB, Sab, we have  $AB : ab :: SB : Sb$ ; and by reason of the similar triangles SBC, Sbc, we have  $SB : Sb :: BC : bc$ ; hence  $AB : ab :: BC : bc$ ; we might likewise have  $BC : bc :: CD : cd$ , and so on. Hence the polygons ABCDE, *abcde* have their angles respectively equal and their homologous sides proportional; hence they are similar.

*Cor. 1.* Let  $S\text{-}ABCDE$ ,  $S\text{-}XYZ$  be two pyramids, having a common vertex and the same altitude, or having their bases situated in the same plane; if these pyramids are cut by a plane parallel to the plane of their bases, giving the sections  $abcde$ ,  $xyz$ , then will the sections  $abcde$ ,  $xyz$ , be to each other as the bases  $ABCDE$ ,  $XYZ$ .

For, the polygons  $ABCDE$ ,  $abcde$ , being similar, their surfaces are as the squares of the homologous sides  $AB$ ,  $ab$ ; but  $AB : ab :: SA : Sa$ ; hence  $ABCDE : abcde :: SA^2 : Sa^2$ . For the same reason,  $XYZ : xyz :: SX^2 : Sx^2$ . But since  $abc$  and  $xyz$  are in one plane, we have likewise  $SA : Sa :: SX : Sx$  (Book VI. Prop. XV.); hence  $ABCDE : abcde :: XYZ : xyz$ ; hence the sections  $abcde$ ,  $xyz$ , are to each other as the bases  $ABCDE$ ,  $XYZ$ .

*Cor. 2.* If the bases  $ABCDE$ ,  $XYZ$ , are equivalent, any sections  $abcde$ ,  $xyz$ , made at equal distances from the bases, will be equivalent likewise.

#### PROPOSITION IV. THEOREM.

*The convex surface of a regular pyramid is equal to the perimeter of its base multiplied by half the slant height.*

For, since the pyramid is regular, the point  $O$ , in which the axis meets the base, is the centre of the polygon  $ABCDE$  (Def. 14.); hence the lines  $OA$ ,  $OB$ ,  $OC$ , &c. drawn to the vertices of the base, are equal.

In the right angled triangles  $SAO$ ,  $SBO$ , the bases and perpendiculars are equal: since the hypotenuses are equal: and it may be proved in the same way that all the sides of the right pyramid are equal. The triangles, therefore, which form the convex surface of the prism are all equal to each other. But the area of either of these triangles, as  $ESA$ , is equal

to its base  $EA$  multiplied by half the perpendicular  $SF$ , which is the slant height of the pyramid : hence the area of all the triangles, or the convex surface of the pyramid, is equal to the perimeter of the base multiplied by half the slant height.

*Cor.* The convex surface of the frustum of a regular pyramid is equal to half the perimeters of its upper and lower bases multiplied by its slant height.

For, since the section  $abcde$  is similar to the base (Prop. III.), and since the base  $ABCDE$  is a regular polygon (Def. 14.), it follows that the sides  $ea$ ,  $ab$ ,  $bc$ ,  $cd$  and  $de$  are all equal to each other. Hence the convex surface of the frustum  $ABCDE-d$  is formed by the equal trapezoids  $EAae$ ,  $ABba$ , &c. and the perpendicular distance between the parallel sides of either of these trapezoids is equal to  $Ff$ , the slant height of the frustum. But the area of either of the trapezoids, as  $AEea$ , is equal to  $\frac{1}{2}(EA + ea) \times Ff$  (Book IV. Prop. VII.) : hence the area of all of them, or the convex surface of the frustum, is equal to half the perimeters of the upper and lower bases multiplied by the slant height.

#### PROPOSITION V. THEOREM.

*If the three planes which form a solid angle of a prism, are equal to the three planes which form the solid angle of another prism, each to each, and are like situated, the two prisms will be equal to each other.*

Let the base  $ABCDE$  be equal to the base  $abcde$ , the parallelogram  $ABGF$  equal to the parallelogram  $abgf$ , and the parallelogram  $BCHG$  equal to  $bchg$ ; then will the prism  $ABCDE-K$  be equal to the prism  $abcde-k$ .

For, lay the base  $ABCDE$  upon its equal  $abcde$ ; these two bases will coincide. But the three plane angles which form

the solid angle  $B$ , are respectively equal to the three plane angles, which form the solid angle  $b$ , namely,  $ABC = abc$ ,  $ABG = abg$ , and  $GBC = gbc$ ; they are also similarly situated. hence the solid angles  $B$  and  $b$  are equal (Book VI. Prop. XXI. Sch.); and therefore the side  $BG$  will fall on its equal  $bg$ . It is likewise evident, that by reason of the equal parallelograms  $ABGF$ ,  $abgf$ , the side  $GF$  will fall on its equal  $gf$ , and in the same manner  $GH$  on  $gh$ ; hence, the plane of the upper base,  $FGHIK$  will coincide with the plane  $fg hik$  (Book VI. Prop. II.).

But the two upper bases being equal to their corresponding lower bases, are equal to each other: hence  $HI$  will coincide with  $hi$ ,  $IK$  with  $ik$ , and  $KF$  with  $kf$ ; and therefore the lateral faces of the prisms will coincide: therefore, the two prisms coinciding throughout are equal (Ax. 13.).

*Cor. Two right prisms, which have equal bases and equal altitudes, are equal.* For, since the side  $AB$  is equal to  $ab$ , and the altitude  $BG$  to  $bg$ , the rectangle  $ABGF$  will be equal to  $abgf$ ; so also will the rectangle  $BGHC$  be equal to  $bghc$ ; and thus the three planes, which form the solid angle  $B$ , will be equal to the three which form the solid angle  $b$ . Hence the two prisms are equal.

#### PROPOSITION VI. THEOREM.

*In every parallelepipedon the opposite planes are equal and parallel.*

By the definition of this solid, the bases  $ABCD$ ,  $EFGH$ , are equal parallelograms, and their sides are parallel: it remains only to show, that the same is true of any two opposite lateral faces, such as  $AEHD$ ,  $BFGC$ . Now  $AD$  is equal and parallel to  $BC$ , because the figure  $ABCD$  is a par-

allelogram; for a like reason,  $AE$  is parallel to  $BF$ : hence the angle  $DAE$  is equal to the angle  $CBF$ , and the planes  $DAE$ ,  $CBF$ , are parallel (Book VI. Prop. XIII.) ; hence also the parallelogram  $DAEH$  is equal to the parallelogram  $CBFG$ . In the same way, it might be shown that the opposite parallelograms  $ABFE$ ,  $DCGH$ , are equal and parallel.

*Cor. 1.* Since the parallelopipedon is a solid bounded by six planes, whereof those lying opposite to each other are equal and parallel, it follows that any face and the one opposite to it, may be assumed as the bases of the parallelopipedon.

*Cor. 2.* *The diagonals of a parallelopipedon bisect each other.* For, suppose two diagonals  $EC$ ,  $AG$ , to be drawn both through opposite vertices: since  $AE$  is equal and parallel to  $CG$ , the figure  $AEGC$  is a parallelogram; hence the diagonals  $EC$ ,  $AG$  will mutually bisect each other. In the same manner, we could show that the diagonal  $EC$  and another  $DF$  bisect each other; hence the four diagonals will mutually bisect each other, in a point which may be regarded as the centre of the parallelopipedon.

*Scholium.* If three straight lines  $AB$ ,  $AE$ ,  $AD$ , passing through the same point  $A$ , and making given angles with each other, are known, a parallelopipedon may be formed on those lines. For this purpose, a plane must be passed through the extremity of each line, and parallel to the plane of the other two; that is, through the point  $B$  a plane parallel to  $DAE$ , through  $D$  a plane parallel to  $BAE$ , and through  $E$  a plane parallel to  $BAD$ . The mutual intersections of these planes will form the parallelopipedon required.

#### PROPOSITION VII. THEOREM.

*The two triangular prisms into which a parallelopipedon is divided by a plane passing through its opposite diagonal edges, are equivalent.*

Let the parallelopipedon  $ABCD-H$  be divided by the plane  $BDHF$  passing through its diagonal edges : then will the triangular prism  $ABD-H$  be equivalent to the triangular prism  $BCD-H$ .

Through the vertices  $B$  and  $F$ , draw the planes  $Badc$ ,  $Fehg$ , at right angles to the side  $BF$ , the former meeting  $AE$ ,  $DH$ ,  $CG$ , the three other sides of the parallelopipedon, in the points  $a$ ,  $d$ ,  $c$ , the latter in  $e$ ,  $h$ ,  $g$  : the sections  $Badc$ ,  $Fehg$ , will be equal parallelograms. They are equal, because they are formed by planes perpendicular to the same straight line, and consequently parallel (Prop. II.); they are parallelograms, because  $aB$ ,  $dc$ , two opposite sides of the same section, are formed by the meeting of one plane with two parallel planes  $ABFE$ ,  $DCGH$ .

For a like reason, the figure  $BaeF$  is a parallelogram ; so also are  $BFgc$ ,  $cdhg$ ,  $adhe$ , the other lateral faces of the solid  $Badc-g$  ; hence that solid is a prism (Def. 6.) ; and that prism is right, because the side  $BF$  is perpendicular to its base.

But the right prism  $Badc-g$  is divided by the plane  $BH$  into two equal right prisms  $Bad-h$ ,  $Bcd-h$  ; for, the bases  $Bad$ ,  $Bcd$ , of these prisms are equal, being halves of the same parallelogram, and they have the common altitude  $BF$ , hence they are equal (Prop. V. Cor.).

It is now to be proved that the oblique triangular prism  $ABD-H$  will be equivalent to the right triangular prism  $Bad-h$  ; and since those prisms have a common part  $ABD-h$ , it will only be necessary to prove that the remaining parts, namely, the solids  $BaADd$ ,  $FeEHh$ , are equivalent.

Now, by reason of the parallelograms  $ABFE$ ,  $aBF e$ , the sides  $AE$ ,  $ae$ , being equal to their parallel  $BF$ , are equal to each other ; and taking away the common part  $Ae$ , there remains  $Aa = Ee$ . In the same manner we could prove  $Dd = Hh$ .

Next, to bring about the superposition of the two solids  $BaADd$ ,  $FeEHh$ , let us place the base  $Feh$  on its equal  $Bad$  : the point  $e$  falling on  $a$ , and the point  $h$  on  $d$ , the sides  $eE$ ,  $hH$ , will fall on their equals  $aA$ ,  $dD$ , because they are perpendicular to the same plane  $Bad$ . Hence the two solids in question will coincide exactly with each other ; hence the oblique prism  $BAD-H$ , is equivalent to the right one  $Bad-h$ .

In the same manner might the oblique prism  $BCD-H$ , be proved equivalent to the right prism  $Bcd-h$ . But the two right prisms  $Bad-h$ ,  $Bcd-h$ , are equal, since they have the same altitude  $BF$ , and since their bases  $Bad$ ,  $Bdc$ , are halves of the same parallelogram (Prop. V. Cor.). Hence the two trian-

gular prisms  $BAD-H$ ,  $BDC-G$ , being equivalent to the equal right prisms, are equivalent to each other.

*Cor.* Every triangular prism  $ABD-HEF$  is half of the parallelepipedon  $AG$  described with the same solid angle  $A$ , and the same edges  $AB$ ,  $AD$ ,  $AE$ .

PROPOSITION VIII. THEOREM.

*If two parallelepipedons have a common base, and their upper bases in the same plane and between the same parallels, they will be equivalent.*

Let the parallelepipedons  $AG$ ,  $AL$ , have the common base  $AC$ , and their upper bases  $EG$ ,  $MK$ , in the same plane, and between the same parallels  $HL$ ,  $EK$ ; then will they be equivalent.

There may be three cases, according as  $EI$  is

greater, less than, or equal to,  $EF$ ; but the demonstration is the same for all. In the first place, then we shall show that the triangular prism  $AEI-MDH$ , is equal to the triangular prism  $BFK-LCG$ .

Since  $AE$  is parallel to  $BF$ , and  $HE$  to  $GF$ , the angle  $AEI = BFK$ ,  $HEI = GFK$ , and  $HEA = GFB$ . Also, since  $EF$  and  $IK$  are each equal to  $AB$ , they are equal to each other. To each add  $FI$ , and there will result  $EI$  equal to  $FK$ : hence the triangle  $AEI$  is equal to the triangle  $BFK$  (Bk. I. Prop. V), and the parallelogram  $EM$  to the parallelogram  $FL$ . But the parallelogram  $AH$  is equal to the parallelogram  $CF$  (Prop. VI): hence, the three planes which form the solid angle at  $E$  are respectively equal to the three which form the solid angle at  $F$ , and being like placed, the triangular prism  $AEI-M$  is equal to the triangular prism  $BFK-L$ .

But if the prism  $AEI-M$  is taken away from the solid  $AL$ , there will remain the parallelepipedon  $BADC-L$ ; and if the prism  $BFK-L$  is taken away from the same solid, there will remain the parallelepipedon  $BADC-G$ ; hence those two parallelepipedons  $BADC-L$ ,  $BADC-G$ , are equivalent.

## PROPOSITION IX. THEOREM.

*Two parallelopipedons, having the same base and the same altitude, are equivalent.*

Let  $ABCD$  be the common base of the two parallelopipedons  $AG$ ,  $AL$ ; since they have the same altitude, their upper bases  $EFGH$ ,  $IKLM$ , will be in the same plane. Also the sides  $EF$  and  $AB$  will be equal and parallel, as well as  $IK$  and  $AB$ ; hence  $EF$  is equal and parallel to  $IK$ ; for a like reason,  $GF$  is equal and parallel to  $LK$ .

Let the sides  $EF$ ,  $GH$ , be produced, and likewise  $KL$ ,  $IM$ , till by their intersections they form the parallelogram  $NOPQ$ ; this parallelogram will evidently be equal to either of the bases  $EFGH$ ,  $IKLM$ . Now if a third parallelopipedon be conceived, having for its lower base the parallelogram  $ABCD$ , and  $NOPQ$  for its upper, the third parallelopipedon will be equivalent to the parallelopipedon  $AG$ , since with the same lower base, their upper bases lie in the same plane and between the same parallels,  $GQ$ ,  $FN$  (Prop. VIII.). For the same reason, this third parallelopipedon will also be equivalent to the parallelopipedon  $AL$ ; hence the two parallelopipedons  $AG$ ,  $AL$ , which have the same base and the same altitude, are equivalent.

## PROPOSITION X. THEOREM.

*Any parallelopipedon may be changed into an equivalent rectangular parallelopipedon having the same altitude and an equivalent base.*

Let  $AG$  be the parallelopipedon proposed. From the points  $A, B, C, D$ , draw  $AI, BK, CL, DM$ , perpendicular to the plane of the base; you will thus form the parallelopipedon  $AL$  equivalent to  $AG$ , and having its lateral faces  $AK, BL, \&c.$  rectangles. Hence if the base  $ABCD$  is a rectangle,  $AL$  will be a rectangular parallelopipedon equivalent to  $AG$ , and consequently,

the parallelopipedon required. But if  $ABCD$  is not a rectangle, draw  $AO$  and  $BN$  perpendicular to  $CD$ , and  $OQ$  and  $NP$  perpendicular to the base; you will then have the solid  $ABNO-IKPQ$ , which will be a rectangular parallelopipedon: for by construction, the bases  $ABNO$ , and  $IKPQ$  are rectangles; so also are the lateral faces, the edges  $AI, OQ, \&c.$  being perpendicular to the plane of the base; hence the solid  $AP$  is a rectangular parallelopipedon. But the two parallelopipedons  $AP, AL$  may be conceived as having the same base  $ABKI$  and the same altitude  $AO$ : hence the parallelopipedon  $AG$ , which was at first changed into an equivalent parallelopipedon  $AL$ , is again changed into an equivalent rectangular parallelopipedon  $AP$ , having the same altitude  $AI$ , and a base  $ABNO$  equivalent to the base  $ABCD$ .

#### PROPOSITION XI. THEOREM.

*Two rectangular parallelopipedons, which have the same base, are to each other as their altitudes.*

Let the parallelopipedons AG, AL, have the same base BD; then will they be to each other as their altitudes AE, AI.

First, suppose the altitudes AE, AI, to be to each other as two whole numbers, as 15 is to 8, for example. Divide AE into 15 equal parts; whereof AI will contain 8; and through  $x, y, z$ , &c. the points of division, draw planes parallel to the base. These planes will cut the solid AG into 15 partial parallelopipedons, all equal to each other, because they have equal bases and equal altitudes—equal bases, since every section MIKL, made parallel to the base ABCD of a prism, is equal to that base (Prop. II.), equal altitudes, because the altitudes are the equal divisions  $Ax, xy, yz$ , &c. But of those 15 equal parallelopipedons, 8 are contained in AL; hence the solid AG is to the solid AL as 15 is to 8, or generally, as the altitude AE is to the altitude AI.

Again, if the ratio of AE to AI cannot be exactly expressed in numbers, it is to be shown, that notwithstanding, we shall have

$$\text{solid AG} : \text{solid AL} :: \text{AE} : \text{AI}.$$

For, if this proportion is not correct, suppose we have

$$\text{sol. AG} : \text{sol. AL} :: \text{AE} : \text{AO greater than AI}.$$

Divide AE into equal parts, such that each shall be less than OI; there will be at least one point of division  $m$ , between O and I. Let P be the parallelopipedon, whose base is ABCD, and altitude  $Am$ ; since the altitudes AE,  $Am$ , are to each other as the two whole numbers, we shall have

$$\text{sol. AG} : P :: \text{AE} : Am.$$

But by hypothesis, we have

$$\text{sol. AG} : \text{sol. AL} :: \text{AE} : \text{AO};$$

therefore,

$$\text{sol. AL} : P :: \text{AO} : Am.$$

But AO is greater than  $Am$ ; hence if the proportion is correct, the solid AL must be greater than P. On the contrary, however, it is less: hence the fourth term of this proportion

$$\text{sol. AG} : \text{sol. AL} :: \text{AE} : x,$$

cannot possibly be a line greater than AI. By the same mode of reasoning, it might be shown that the fourth term cannot be less than AI; therefore it is equal to AI; hence rectangular parallelopipedons having the same base are to each other as their altitudes.

## PROPOSITION XII. THEOREM.

*Two rectangular parallelopipeds, having the same altitude are to each other as their bases.*

Let the parallelopipeds AG, AK, have the same altitude AE; then will they be to each other as their bases AC, AN.

Having placed the two solids by the side of each other, as the figure represents, produce the plane ONKL till it meets the plane DCGH in PQ; you will thus have a third parallelopipeton AQ, which may be compared with each of the parallelopipeds AG, AK. The two solids AG, AQ, having the same base AEHD are to each other as their altitudes AB, AO; in like manner, the two solids AQ, AK, having the same base AOLE, are to each other as their altitudes AD, AM. Hence we have the two proportions,

$$\begin{aligned} \text{sol. AG} : \text{sol. AQ} &:: \text{AB} : \text{AO}, \\ \text{sol. AQ} : \text{sol. AK} &:: \text{AD} : \text{AM}. \end{aligned}$$

Multiplying together the corresponding terms of these proportions, and omitting in the result the common multiplier *sol. AQ*; we shall have

$$\text{sol. AG} : \text{sol. AK} :: \text{AB} \times \text{AD} : \text{AO} \times \text{AM}.$$

But  $\text{AB} \times \text{AD}$  represents the base ABCD; and  $\text{AO} \times \text{AM}$  represents the base AMNO; hence two rectangular parallelopipeds of the same altitude are to each other as their bases.

## PROPOSITION XIII. THEOREM.

*Any two rectangular parallelopipeds are to each other as the products of their bases by their altitudes, that is to say, as the products of their three dimensions.*

For, having placed the two solids AG, AZ, so that their surfaces have the common angle BAE, produce the planes necessary for completing the third parallelopipedon AK having the same altitude with the parallelopipedon AG. By the last proposition, we shall have

$$\text{sol. AG} : \text{sol. AK} :: \text{ABCD} : \text{AMNO}.$$

But the two parallelopipedons AK, AZ, having the same base AMNO, are to each other as their altitudes AE, AX; hence we have

$$\text{sol. AK} : \text{sol. AZ} :: \text{AE} : \text{AX}.$$

Multiplying together the corresponding terms of these proportions, and omitting in the result the common multiplier *sol. AK*; we shall have

$$\text{sol. AG} : \text{sol. AZ} :: \text{ABCD} \times \text{AE} : \text{AMNO} \times \text{AX}.$$

Instead of the bases ABCD and AMNO, put  $\text{AB} \times \text{AD}$  and  $\text{AO} \times \text{AM}$  it will give

$$\text{sol. AG} : \text{sol. AZ} :: \text{AB} \times \text{AD} \times \text{AE} : \text{AO} \times \text{AM} \times \text{AX}.$$

Hence any two rectangular parallelopipedons are to each other, &c.

*Scholium.* We are consequently authorized to assume, as the measure of a rectangular parallelopipedon, the product of its base by its altitude, in other words, the product of its three dimensions.

In order to comprehend the nature of this measurement, it is necessary to reflect, that the number of linear units in one dimension of the base multiplied by the number of linear units in the other dimension of the base, will give the number of superficial units in the base of the parallelopipedon (Book IV. Prop. IV. Sch.). For each unit in height there are evidently as many solid units as there are superficial units in the base. Therefore, the number of superficial units in the base multiplied by the number of linear units in the altitude, gives the number of solid units in the parallelopipedon.

If the three dimensions of another parallelopipedon are valued according to the same linear unit, and multiplied together in the same manner, the two products will be to each other as

the solids, and will serve to express their relative magnitude.

The magnitude of a solid, its volume or extent, forms what is called its *solidity*; and this word is exclusively employed to designate the measure of a solid: thus we say the solidity of a rectangular parallelopipedon is equal to the product of its base by its altitude, or to the product of its three dimensions.

As the cube has all its three dimensions equal, if the side is 1, the solidity will be  $1 \times 1 \times 1 = 1$ : if the side is 2, the solidity will be  $2 \times 2 \times 2 = 8$ ; if the side is 3, the solidity will be  $3 \times 3 \times 3 = 27$ ; and so on: hence, if the sides of a series of cubes are to each other as the numbers 1, 2, 3, &c. the cubes themselves or their solidities will be as the numbers 1, 8, 27, &c. Hence it is, that in arithmetic, the *cube* of a number is the name given to a product which results from three factors, each equal to this number.

If it were proposed to find a cube double of a given cube, the side of the required cube would have to be to that of the given one, as the cube-root of 2 is to unity. Now, by a geometrical construction, it is easy to find the square root of 2; but the cube-root of it cannot be so found, at least not by the simple operations of elementary geometry, which consist in employing nothing but straight lines, two points of which are known, and circles whose centres and radii are determined.

Owing to this difficulty the problem of the *duplication of the cube* became celebrated among the ancient geometers, as well as that of the *trisection of an angle*, which is nearly of the same species. The solutions of which such problems are susceptible, have however long since been discovered; and though less simple than the constructions of elementary geometry, they are not, on that account, less rigorous or less satisfactory.

#### PROPOSITION XIV. THEOREM.

*The solidity of a parallelopipedon, and generally of any prism, is equal to the product of its base by its altitude.*

For, in the first place, any parallelopipedon is equivalent to a rectangular parallelopipedon, having the same altitude and an equivalent base (Prop. X.). Now the solidity of the latter is equal to its base multiplied by its height; hence the solidity of the former is, in like manner, equal to the product of its base by its altitude.

In the second place, any triangular prism is half of the parallelopipedon so constructed as to have the same altitude and a double base (Prop. VII.). But the solidity of the latter is equal

to its base multiplied by its altitude ; hence that of a triangular prism is also equal to the product of its base, which is half that of the parallelopipedon, multiplied into its altitude.

In the third place, any prism may be divided into as many triangular prisms of the same altitude, as there are triangles capable of being formed in the polygon which constitutes its base. But the solidity of each triangular prism is equal to its base multiplied by its altitude ; and since the altitude is the same for all, it follows that the sum of all the partial prisms must be equal to the sum of all the partial triangles, which constitute their bases, multiplied by the common altitude.

Hence the solidity of any polygonal prism, is equal to the product of its base by its altitude.

*Cor.* Comparing two prisms, which have the same altitude, the products of their bases by their altitudes will be as the bases simply ; hence *two prisms of the same altitude are to each other as their bases*. For a like reason, *two prisms of the same base are to each other as their altitudes*. And when neither their bases nor their altitudes are equal, their solidities will be to each other as the products of their bases and altitudes.

#### PROPOSITION XV. THEOREM.

*Two triangular pyramids, having equivalent bases and equal altitudes, are equivalent, or equal in solidity.*

Let  $S\text{-}ABC$ ,  $S\text{-}abc$ , be those two pyramids ; let their equivalent bases  $ABC$ ,  $abc$ , be situated in the same plane, and let  $AT$  be their common altitude. If they are not equivalent, let  $S\text{-}abc$

be the smaller : and suppose  $Aa$  to be the altitude of a prism, which having  $ABC$  for its base, is equal to their difference.

Divide the altitude  $AT$  into equal parts  $Ax, xy, yz, \&c.$  each less than  $Aa$ , and let  $k$  be one of those parts ; through the points of division pass planes parallel to the plane of the bases ; the corresponding sections formed by these planes in the two pyramids will be respectively equivalent, namely  $DEF$  to  $def$ ,  $GHI$  to  $ghi$ ,  $\&c.$  (Prop. III. Cor. 2.).

This being granted, upon the triangles  $ABC, DEF, GHI, \&c.$  taken as bases, construct exterior prisms having for edges the parts  $AD, DG, GK, \&c.$  of the edge  $SA$  ; in like manner, on bases  $def, ghi, klm, \&c.$  in the second pyramid, construct interior prisms, having for edges the corresponding parts of  $Sa$ . It is plain that the sum of all the exterior prisms of the pyramid  $S-ABC$  will be greater than this pyramid ; and also that the sum of all the interior prisms of the pyramid  $S-abc$  will be less than this pyramid. Hence the difference, between the sum of all the exterior prisms and the sum of all the interior ones, must be greater than the difference between the two pyramids themselves.

Now, beginning with the bases  $ABC, abc$ , the second exterior prism  $DEF-G$  is equivalent to the first interior prism  $def-a$ , because they have the same altitude  $k$ , and their bases  $DEF, def$ , are equivalent ; for like reasons, the third exterior prism  $GHI-K$  and the second interior prism  $ghi-d$  are equivalent ; the fourth exterior and the third interior ; and so on, to the last in each series. Hence all the exterior prisms of the pyramid  $S-ABC$ , excepting the first prism  $ABC-D$ , have equivalent corresponding ones in the interior prisms of the pyramid  $S-abc$  : hence the prism  $ABC-D$ , is the difference between the sum of all the exterior prisms of the pyramid  $S-ABC$ , and the sum of the interior prisms of the pyramid  $S-abc$ . But the difference between these two sets of prisms has already been proved to be greater than that of the two pyramids ; which latter difference we supposed to be equal to the prism  $a-ABC$  : hence the prism  $ABC-D$ , must be greater than the prism  $a-ABC$ . But in reality it is less ; for they have the same base  $ABC$ , and the altitude  $Ax$  of the first is less than  $Aa$  the altitude of the second. Hence the supposed inequality between the two pyramids cannot exist ; hence the two pyramids  $S-ABC, S-abc$ , having equal altitudes and equivalent bases, are themselves equivalent.

## PROPOSITION XVI. THEOREM.

*Every triangular pyramid is a third part of the triangular prism having the same base and the same altitude.*

Let F-ABC be a triangular pyramid, ABC-DEF a triangular prism of the same base and the same altitude; the pyramid will be equal to a third of the prism.

Cut off the pyramid F-ABC from the prism, by the plane FAC; there will remain the solid F-ACDE, which may be considered as a quadrangular pyramid, whose vertex is F, and whose base is the parallelogram ACDE.

Draw the diagonal CE; and pass the plane FCE, which will cut the quadrangular pyramid into two triangular ones F-ACE, F-CDE. These two triangular pyramids have for their common altitude the perpendicular let fall from F on the plane ACDE; they have equal bases, the triangles ACE, CDE being halves of the same parallelogram; hence the two pyramids F-ACE, F-CDE, are equivalent (Prop. XV.). But the pyramid F-CDE and the pyramid F-ABC have equal bases ABC, DEF; they have also the same altitude, namely, the distance between the parallel planes ABC, DEF; hence the two pyramids are equivalent. Now the pyramid F-CDE has already been proved equivalent to F-ACE; hence the three pyramids F-ABC, F-CDE, F-ACE, which compose the prism ABC-DEF are all equivalent. Hence the pyramid F-ABC is the third part of the prism ABC-DEF, which has the same base and the same altitude.

*Cor.* The solidity of a triangular pyramid is equal to a third part of the product of its base by its altitude.

## PROPOSITION XVII. THEOREM.

*The solidity of every pyramid is equal to the base multiplied by a third of the altitude.*

Let  $S\text{-}ABCDE$  be a pyramid.

Pass the planes  $SEB$ ,  $SEC$ , through the diagonals  $EB$ ,  $EC$ ; the polygonal pyramid  $S\text{-}ABCDE$  will be divided into several triangular pyramids all having the same altitude  $SO$ . But each of these pyramids is measured by multiplying its base  $ABE$ ,  $BCE$ , or  $CDE$ , by the third part of its altitude  $SO$  (Prop. XVI. Cor.); hence the sum of these triangular pyramids, or the polygonal pyramid  $S\text{-}ABCDE$  will be measured by the sum of the triangles  $ABE$ ,  $BCE$ ,  $CDE$ , or the polygon  $ABCDE$ , multiplied by one third of  $SO$ ; hence every pyramid is measured by a third part of the product of its base by its altitude.

*Cor. 1.* Every pyramid is the third part of the prism which has the same base and the same altitude.

*Cor. 2.* Two pyramids having the same altitude are to each other as their bases.

*Cor. 3.* Two pyramids having equivalent bases are to each other as their altitudes.

*Cor. 4.* Pyramids are to each other as the products of their bases by their altitudes.

*Scholium.* The solidity of any polyedral body may be computed, by dividing the body into pyramids; and this division may be accomplished in various ways. One of the simplest is to make all the planes of division pass through the vertex of one solid angle; in that case, there will be formed as many partial pyramids as the polyedron has faces, *minus* those faces which form the solid angle whence the planes of division proceed.

#### PROPOSITION XVIII. THEOREM.

*If a pyramid be cut by a plane parallel to its base, the frustum that remains when the small pyramid is taken away, is equivalent to the sum of three pyramids having for their common altitude the altitude of the frustum, and for bases the lower base of the frustum, the upper base, and a mean proportional between the two bases.*

L

Let  $S\text{-}ABCDE$  be a pyramid cut by the plane  $abcde$ , parallel to its base; let  $T\text{-}FGH$  be a triangular pyramid having the same altitude and an equivalent base with the pyramid  $S\text{-}ABCDE$ . The two bases may be regarded as situated in the same plane; in which case, the plane  $abcd$ , if produced, will form in the triangular pyramid a section  $fgh$  situated at the same distance above the common plane of the bases; and therefore the section  $fgh$  will be to the section  $abcde$  as the base  $FGH$  is to the base  $ABD$  (Prop. III.), and since the bases are equivalent, the sections will be so likewise. Hence the pyramids  $S\text{-}abcde$ ,  $T\text{-}fgh$  are equivalent, for their altitude is the same and their bases are equivalent. The whole pyramids  $S\text{-}ABCDE$ ,  $T\text{-}FGH$  are equivalent for the same reason; hence the frustums  $ABD\text{-}dab$ ,  $FGH\text{-}hfg$  are equivalent; hence if the proposition can be proved in the single case of the frustum of a triangular pyramid, it will be true of every other.

Let  $FGH\text{-}hfg$  be the frustum of a triangular pyramid, having parallel bases: through the three points  $F, g, H$ , pass the plane  $FgH$ ; it will cut off from the frustum the triangular pyramid  $g\text{-}FGH$ . This pyramid has for its base the lower base  $FGH$  of the frustum; its altitude likewise is that of the frustum, because the vertex  $g$  lies in the plane of the upper base  $fgh$ .

This pyramid being cut off, there will remain the quadrangular pyramid  $g\text{-}fhHF$ , whose vertex is  $g$ , and base  $fhHF$ . Pass the plane  $fgH$  through the three points  $f, g, H$ ; it will divide the quadrangular pyramid into two triangular pyramids  $g\text{-}FfH$ ,  $g\text{-}fhH$ . The latter has for its base the upper base  $gfh$  of the frustum; and for its altitude, the altitude of the frustum, because its vertex  $H$  lies in the lower base. Thus we already know two of the three pyramids which compose the frustum.

It remains to examine the third  $g\text{-}FfH$ . Now, if  $gK$  be drawn parallel to  $fF$ , and if we conceive a new pyramid  $K\text{-}FfH$ , having  $K$  for its vertex and  $FfH$  for its base, these two pyramids will have the same base  $FfH$ ; they will also have the same altitude, because their vertices  $g$  and  $K$  lie in the line  $gK$ , parallel to  $Ff$ , and consequently parallel to the

plane of the base : hence these pyramids are equivalent. But the pyramid  $K\text{-}FfH$  may be regarded as having its vertex in  $f$ , and thus its altitude will be the same as that of the frustum : as to its base  $FKH$ , we are now to show that this is a mean proportional between the bases  $FGH$  and  $fgh$ . Now, the triangles  $FHK$ ,  $fgh$ , have each an equal angle  $F=f$  ; hence

$FHK : fgh :: FK \times FH : fg \times fh$  (Book IV. Prop. XXIV.) ; but because of the parallels,  $FK=fg$ , hence

$$FHK : fgh :: FH : fh.$$

We have also,

$$FHG : FHK :: FG : FK \text{ or } fg.$$

But the similar triangles  $FGH$ ,  $fgh$  give

$$FG : fg :: FH : fh ;$$

hence,

$$FGH : FHK :: FHK : fgh ;$$

or the base  $FHK$  is a mean proportional between the two bases  $FGH$ ,  $fgh$ . Hence the frustum of a triangular pyramid is equivalent to three pyramids whose common altitude is that of the frustum and whose bases are the lower base of the frustum, the upper base, and a mean proportional between the two bases.

#### PROPOSITION XIX. THEOREM.

*Similar triangular prisms are to each other as the cubes of their homologous sides.*

Let  $CBD\text{-}P$ ,  $cbd\text{-}p$ , be two similar triangular prisms, of which  $BC$ ,  $bc$ , are homologous sides : then will the prism  $CBD\text{-}P$  be to the prism  $cbd\text{-}p$ , as  $BC^3$  to  $bc^3$ .

For, since the prisms are similar, the planes which contain the homologous solid angles  $B$  and  $b$ , are similar, like placed, and equally inclined to each other (Def. 17.) : hence the solid angles  $B$  and  $b$ , are equal (Book VI. Prop. XXI. Sch.). If these solid angles be applied to each other, the angle  $cbd$  will coincide with  $CBD$ , the side  $ba$  with  $BA$ , and the prism  $cbd\text{-}p$  will take the position  $Bcd\text{-}p$ . From  $A$  draw  $AH$  perpendicular to the common base of the prisms : then will the plane  $BAH$  be perpendicular to the plane of the com-

mon base (Book VI. Prop. XVI.). Through  $a$ , in the plane  $BAH$ , draw  $ah$  perpendicular to  $BH$ : then will  $ah$  also be perpendicular to the base  $BDC$  (Book VI. Prop. XVII.); and  $AH$ ,  $ah$  will be the altitudes of the two prisms.

Now, because of the similar triangles  $ABH$ ,  $aBh$ , and of the similar parallelograms  $AC$ ,  $ac$ , we have

$$AH : ah :: AB : ab :: BC : bc.$$

But since the bases are similar, we have

*base*  $BCD$  : *base*  $bcd$  ::  $BC^2$  :  $bc^2$  (Book IV. Prop. XXV.); hence,

$$\text{base } BCD : \text{base } bcd :: AH^2 : ah^2.$$

Multiplying the antecedents by  $AH$ , and the consequents by  $ah$ , and we have

$$\text{base } BCD \times AH : \text{base } bcd \times ah :: AH^3 : ah^3.$$

But the solidity of a prism is equal to the base multiplied by the altitude (Prop. XIV.); hence, the

*prism*  $BCD-P$  : *prism*  $bcd-p$  ::  $AH^3$  :  $ah^3$  ::  $BC^3$  :  $bc^3$ ,  
or as the cubes of any other of their homologous sides.

*Cor.* Whatever be the bases of similar prisms, the prisms will be to each other as the cubes of their homologous sides.

For, since the prisms are similar, their bases will be similar polygons (Def. 17.); and these similar polygons may be divided into an equal number of similar triangles, similarly placed (Book IV. Prop. XXVI.): therefore the two prisms may be divided into an equal number of triangular prisms, having their faces similar and like placed; and therefore, equally inclined (Book VI. Prop. XXI.); hence the prisms will be similar. But these triangular prisms will be to each other as the cubes of their homologous sides, which sides being proportional, the sums of the triangular prisms, that is, the polygonal prisms, will be to each other as the cubes of their homologous sides.

#### PROPOSITION XX. THEOREM.

*Two similar pyramids are to each other as the cubes of their homologous sides.*

For, since the pyramids are similar, the solid angles at the vertices will be contained by the same number of similar planes, like placed, and equally inclined to each other (Def. 17.). Hence, the solid angles at the vertices may be made to coincide, or the two pyramids may be so placed as to have the solid angle  $S$  common.

In that position, the bases  $ABCDE$ ,  $abcde$ , will be parallel; because, since the homologous faces are similar, the angle  $Sab$  is equal to  $SAB$ , and  $Sbc$  to  $SBC$ ; hence the plane  $ABC$  is parallel to the plane  $abc$  (Book VI. Prop. XIII.). This being proved, let  $SO$  be the perpendicular drawn from the vertex  $S$  to the plane  $ABC$ , and  $o$  the point where this perpendicular meets the plane  $abc$ : from what has already been shown, we shall have

$SO : So :: SA : Sa :: AB : ab$  (Prop. III.); and consequently,

$$\frac{1}{3}SO : \frac{1}{3}So :: AB : ab.$$

But the bases  $ABCDE$ ,  $abcde$ , being similar figures, we have

$$ABCDE : abcde :: AB^2 : ab^2 \text{ (Book IV. Prop. XXVII.)}.$$

Multiply the corresponding terms of these two proportions; there results the proportion,

$$ABCDE \times \frac{1}{3}SO : abcde \times \frac{1}{3}So :: AB^3 : ab^3.$$

Now  $ABCDE \times \frac{1}{3}SO$  is the solidity of the pyramid  $S-ABCDE$ , and  $abcde \times \frac{1}{3}So$  is that of the pyramid  $S-abcde$  (Prop. XVII.); hence two similar pyramids are to each other as the cubes of their homologous sides.

### General Scholium.

The chief propositions of this Book relating to the solidity of polyedrons, may be exhibited in algebraical terms, and so recapitulated in the briefest manner possible.

Let  $B$  represent the base of a *prism*;  $H$  its altitude: the solidity of the prism will be  $B \times H$ , or  $BH$ .

Let  $B$  represent the base of a *pyramid*;  $H$  its altitude: the solidity of the pyramid will be  $B \times \frac{1}{3}H$ , or  $H \times \frac{1}{3}B$ , or  $\frac{1}{3}BH$ .

Let  $H$  represent the altitude of the *frustum of a pyramid*, having parallel bases  $A$  and  $B$ ;  $\sqrt{AB}$  will be the mean proportional between those bases; and the solidity of the frustum will be  $\frac{1}{3}H \times (A + B + \sqrt{AB})$ .

In fine, let  $P$  and  $p$  represent the *solidities of two similar prisms or pyramids*;  $A$  and  $a$ , two homologous edges: then we shall have

$$P : p :: A^3 : a^3$$

## BOOK VIII.

## THE THREE ROUND BODIES.

*Definitions.*

1. A *cylinder* is the solid generated by the revolution of a rectangle  $ABCD$ , conceived to turn about the immoveable side  $AB$ .

In this movement, the sides  $AD$ ,  $BC$ , continuing always perpendicular to  $AB$ , describe equal circles  $DHP$ ,  $CGQ$ , which are called the *bases of the cylinder*, the side  $CD$  at the same time describing the *convex surface*.

The immoveable line  $AB$  is called the *axis of the cylinder*.

Every section  $KLM$ , made in the cylinder, at right angles to the axis, is a circle equal to either of the bases; for, whilst the rectangle  $ABCD$  turns about  $AB$ , the line  $KI$ , perpendicular to  $AB$ , describes a circle, equal to the base, and this circle is nothing else than the section made perpendicular to the axis at the point  $I$ .

Every section  $PQG$ , made through the axis, is a rectangle double of the generating rectangle  $ABCD$ .

2. A *cone* is the solid generated by the revolution of a right-angled triangle  $SAB$ , conceived to turn about the immoveable side  $SA$ .

In this movement, the side  $AB$  describes a circle  $BDCE$ , named the *base of the cone*; the hypotenuse  $SB$  describes the *convex surface of the cone*.

The point  $S$  is named the *vertex of the cone*,  $SA$  the *axis* or the *altitude*, and  $SB$  the *side* or the *apothem*.

Every section  $HKFI$ , at right angles to the axis, is a circle; every section  $SDE$ , through the axis, is an isosceles triangle double of the generating triangle  $SAB$ .

3. If from the cone  $S-CDB$ , the cone  $S-FKH$  be cut off by a plane parallel to the base, the remaining solid  $CBHF$  is called a *truncated cone*, or the *frustum of a cone*.

We may conceive it to be generated by the revolution of a trapezoid ABHG, whose angles A and G are right angles, about the side AG. The immoveable line AG is called the *axis* or *altitude of the frustum*, the circles BDC, HEK, are its *bases*, and BH is its *side*.

4. Two cylinders, or two cones, are *similar*, when their axes are to each other as the diameters of their bases.

5. If in the circle ACD, which forms the base of a cylinder, a polygon ABCDE be inscribed, a right prism, constructed on this base ABCDE, and equal in altitude to the cylinder, is said to be *inscribed in the cylinder*, or the cylinder to be *circumscribed about the prism*.

The edges AF, BG, CH, &c. of the prism, being perpendicular to the plane of the base, are evidently included in the convex surface of the cylinder; hence the prism and the cylinder touch one another along these edges.

6. In like manner, if ABCD is a polygon, circumscribed about the base of a cylinder, a right prism, constructed on this base ABCD, and equal in altitude to the cylinder, is said to be *circumscribed about the cylinder*, or the cylinder to be *inscribed in the prism*.

Let M, N, &c. be the points of contact in the sides AB, BC, &c.; and through the points M, N, &c. let MX, NY, &c. be drawn perpendicular to the plane of the base: these perpendiculars will evidently lie both in the surface of the cylinder, and in that of the circumscribed prism; hence they will be their lines of contact.

7. If in the circle ABCDE, which forms the base of a cone, any polygon ABCDE be inscribed, and from the vertices A, B, C, D, E, lines be drawn to S, the vertex of the cone, these lines may be regarded as the sides of a pyramid whose base is the polygon ABCDE and vertex S. The sides of this pyramid are in the convex surface of the cone, and the pyramid is said to be *inscribed in the cone*.

## PROPOSITION I. THEOREM.

*The convex surface of a cylinder is equal to the circumference of its base multiplied by its altitude.*

Let  $CA$  be the radius of the given cylinder's base, and  $H$  its altitude : the circumference whose radius is  $CA$  being represented by *circ. CA*, we are to show that the convex surface of the cylinder is equal to *circ. CA*  $\times H$ .

Inscribe in the circle any regular polygon,  $BDEFGA$ , and construct on this polygon a right prism having its altitude equal to  $H$ , the altitude of the cylinder : this prism will be inscribed in the cylinder. The convex surface of the prism is equal to the perimeter of the polygon, multiplied by the altitude  $H$  (Book VII. Prop. I.). Let now the arcs which subtend the sides of the polygon be continually bisected, and the number of sides of the polygon indefinitely increased : the perimeter of the polygon will then become equal to *circ. CA* (Book V. Prop. VIII. Cor. 2.), and the convex surface of the prism will coincide with the convex surface of the cylinder. But the convex surface of the prism is equal to the perimeter of its base multiplied by  $H$ , whatever be the number of sides : hence, the convex surface of the cylinder is equal to the circumference of its base multiplied by its altitude.

## PROPOSITION II. THEOREM.

*The solidity of a cylinder is equal to the product of its base by its altitude.*

Let  $CA$  be the radius of the base of the cylinder, and  $H$  the altitude. Let the circle whose radius is  $CA$  be represented by *area*  $CA$ , it is to be proved that the solidity of the cylinder is equal to *area*  $CA \times H$ .

Inscribe in the circle any regular polygon  $BDEFGA$ , and construct on this polygon a right prism having its altitude equal

to  $H$ , the altitude of the cylinder: this prism will be inscribed in the cylinder. The solidity of the prism will be equal to the area of the polygon multiplied by the altitude  $H$  (Book VII. Prop. XIV.). Let now the number of sides of the polygon be indefinitely increased: the solidity of the new prism will still be equal to its base multiplied by its altitude.

But when the number of sides of the polygon is indefinitely increased, its area becomes equal to the *area*  $CA$ , and its perimeter coincides with *circ.*  $CA$  (Book V. Prop. VIII. Cor. 1. & 2.); the inscribed prism then coincides with the cylinder, since their altitudes are equal, and their convex surfaces perpendicular to the common base: hence the two solids will be equal; therefore the solidity of a cylinder is equal to the product of its base by its altitude.

*Cor. 1.* Cylinders of the same altitude are to each other as their bases; and cylinders of the same base are to each other as their altitudes.

*Cor. 2.* Similar cylinders are to each other as the cubes of their altitudes, or as the cubes of the diameters of their bases. For the bases are as the squares of their diameters; and the cylinders being similar, the diameters of their bases are to each other as the altitudes (Def. 4.); hence the bases are as the squares of the altitudes; hence the bases, multiplied by the altitudes, or the cylinders themselves, are as the cubes of the altitudes.

*Scholium.* Let  $R$  be the radius of a cylinder's base;  $H$  the altitude: the surface of the base will be  $\pi.R^2$  (Book V. Prop. XII. Cor. 2.); and the solidity of the cylinder will be  $\pi R^2 \times H$ , or  $\pi.R^2.H$ .

## PROPOSITION III. THEOREM.

*The convex surface of a cone is equal to the circumference of its base, multiplied by half its side.*

Let the circle  $ABCD$  be the base of a cone,  $S$  the vertex,  $SO$  the altitude, and  $SA$  the side: then will its convex surface be equal to  $\text{circ. } OA \times \frac{1}{2}SA$ .

For, inscribe in the base of the cone any regular polygon  $ABCD$ , and on this polygon as a base conceive a pyramid to be constructed having  $S$  for its vertex: this pyramid will be a regular pyramid, and will be inscribed in the cone.

From  $S$ , draw  $SG$  perpendicular to one of the sides of the polygon. The convex surface of the inscribed pyramid is equal to the perimeter of the polygon which forms its base, multiplied by half the slant height  $SG$  (Book VII. Prop. IV.). Let now the number of sides of the inscribed polygon be indefinitely increased; the perimeter of the inscribed polygon will then become equal to  $\text{circ. } OA$ , the slant height  $SG$  will become equal to the side  $SA$  of the cone, and the convex surface of the pyramid to the convex surface of the cone. But whatever be the number of sides of the polygon which forms the base, the convex surface of the pyramid is equal to the perimeter of the base multiplied by half the slant height: hence the convex surface of a cone is equal to the circumference of the base multiplied by half the side.

*Scholium.* Let  $L$  be the side of a cone,  $R$  the radius of its base; the circumference of this base will be  $2\pi.R$ , and the surface of the cone will be  $2\pi R \times \frac{1}{2}L$ , or  $\pi RL$ .

## PROPOSITION IV. THEOREM.

*The convex surface of the frustum of a cone is equal to its side multiplied by half the sum of the circumferences of its two bases*

Let BIA-DE be a frustum of a cone: then will its convex surface be equal to  $AD \times \left( \frac{\text{circ.} OA + \text{circ.} CD}{2} \right)$ .

For, inscribe in the bases of the frustums two regular polygons of the same number of sides, and having their homologous sides parallel, each to each. The lines joining the vertices of the homologous angles may be regarded as the edges of the frustum of a regular pyramid inscribed in the frustum of the cone. The convex surface of the frustum of the pyramid is equal to half the sum of the perimeters of its bases multiplied by the slant height  $fh$  (Book VII. Prop. IV. Cor.).

Let now the number of sides of the inscribed polygons be indefinitely increased: the perimeters of the polygons will become equal to the circumferences BIA, EGD; the slant height  $fh$  will become equal to the side AD or BE, and the surfaces of the two frustums will coincide and become the same surface.

But the convex surface of the frustum of the pyramid will still be equal to half the sum of the perimeters of the upper and lower bases multiplied by the slant height: hence the surface of the frustum of a cone is equal to its side multiplied by half the sum of the circumferences of its two bases.

*Cor.* Through  $l$ , the middle point of AD, draw  $lKL$  parallel to AB, and  $li$ ,  $Dd$ , parallel to CO. Then, since  $Al$ ,  $lD$ , are equal,  $Ai$ ,  $id$ , will also be equal (Book IV. Prop. XV. Cor. 2.): hence,  $Kl$  is equal to  $\frac{1}{2}(OA + CD)$ . But since the circumferences of circles are to each other as their radii (Book V. Prop. XI.), the  $\text{circ.} Kl = \frac{1}{2}(\text{circ.} OA + \text{circ.} CD)$ ; therefore, the convex surface of a frustum of a cone is equal to its side multiplied by the circumference of a section at equal distances from the two bases.

*Scholium.* If a line AD, lying wholly on one side of the line OC, and in the same plane, make a revolution around OC, the surface described by AD will have for its measure  $AD \times \left( \frac{\text{circ.} AO + \text{circ.} DC}{2} \right)$ , or  $AD \times \text{circ.} lK$ ; the lines AO, DC,  $lK$ , being perpendiculars, let fall from the extremities and from the middle point of AD, on the axis OC.

For, if AD and OC are produced till they meet in S, the surface described by AD is evidently the frustum of a cone

having  $AO$  and  $DC$  for the radii of its bases, the vertex of the whole cone being  $S$ . Hence this surface will be measured as we have said.

This measure will always hold good, even when the point  $D$  falls on  $S$ , and thus forms a whole cone; and also when the line  $AD$  is parallel to the axis, and thus forms a cylinder. In the first case  $DC$  would be nothing; in the second,  $DC$  would be equal to  $AO$  and to  $IK$ .

PROPOSITION V. THEOREM.

*The solidity of a cone is equal to its base multiplied by a third of its altitude.*

Let  $SO$  be the altitude of a cone,  $OA$  the radius of its base, and let the area of the base be designated by *area*  $OA$ : it is to be proved that the solidity of the cone is equal to *area*  $OA \times \frac{1}{3}SO$ .

Inscribe in the base of the cone any regular polygon  $ABDEF$ , and join the vertices  $A, B, C, \&c.$  with the vertex  $S$  of the cone: then will there be inscribed in the cone a regular pyramid having the same vertex as the cone, and having for its base the polygon  $ABDEF$ . The solidity of this pyramid is equal to its base multiplied by one third of its altitude (Book VII. Prop. XVII.). Let now the number of sides of the polygon be indefinitely increased: the polygon will then become equal to the circle, and the pyramid and cone will coincide and become equal. But the solidity of the pyramid is equal to its base multiplied by one third of its altitude, whatever be the number of sides of the polygon which forms its base: hence the solidity of the cone is equal to its base multiplied by a third of its altitude.

*Cor.* A cone is the third of a cylinder having the same base and the same altitude; whence it follows,

1. That cones of equal altitudes are to each other as their bases;

2. That cones of equal bases are to each other as their altitudes;

3. That similar cones are as the cubes of the diameters of their bases, or as the cubes of their altitudes.

*Cor. 2.* The solidity of a cone is equivalent to the solidity of a pyramid having an equivalent base and the same altitude (Book VII. Prop. XVII.).

*Scholium.* Let  $R$  be the radius of a cone's base,  $H$  its altitude; the solidity of the cone will be  $\pi R^2 \times \frac{1}{3}H$ , or  $\frac{1}{3}\pi R^2 H$ .

#### PROPOSITION VI. THEOREM

*The solidity of the frustum of a cone is equal to the sum of the solidities of three cones whose common altitude is the altitude of the frustum, and whose bases are, the upper base of the frustum, the lower base of the frustum, and a mean proportional between them.*

Let  $AEB-CD$  be the frustum of a cone, and  $OP$  its altitude; then will its solidity be equal to

$$\frac{1}{3}\pi \times OP \times (AO^2 + DP^2 + AO \times DP).$$

For, inscribe in the lower and upper bases two regular polygons having the same number of sides, and having their homologous sides parallel, each to each. Join the vertices of the homologous angles and there will then be inscribed in the frustum of the cone, the frustum of a regular pyramid. The solidity of

the frustum of the pyramid is equivalent to three pyramids having the common altitude of the frustum, and for bases, the lower base of the frustum, the upper base of the frustum, and a mean proportional between them (Book VII. Prop. XVIII.).

Let now, the number of sides of the inscribed polygons be indefinitely increased: the bases of the frustum of the pyramid will then coincide with the bases of the frustum of the cone, and the two frustums will coincide and become the same solid. Since the area of a circle is equal to  $R^2 \cdot \pi$  (Book V. Prop. XII. Cor. 2.), the expression for the solidities of the frustum will become

$$\text{for the first pyramid} \quad \frac{1}{3}OP \times OA^2 \cdot \pi.$$

$$\text{for the second} \quad \frac{1}{3}OP \times PD^2 \cdot \pi$$

$$\text{for the third} \quad \frac{1}{3}OP \times AO \times PD \cdot \pi; \text{ since}$$

$AO \times PD \cdot \pi$  is a mean proportional between  $OA^2 \cdot \pi$  and  $PD^2 \cdot \pi$ .

Hence the solidity of the frustum of the cone is measured by  $\frac{1}{3}\pi OP \times (OA^2 + PD^2 + AO \times PD)$ .

## PROPOSITION VII. THEOREM.

*Every section of a sphere, made by a plane, is a circle.*

Let  $AMB$  be a section, made by a plane, in the sphere whose centre is  $C$ . From the point  $C$ , draw  $CO$  perpendicular to the plane  $AMB$ ; and different lines  $CM, CM$ , to different points of the curve  $AMB$ , which terminates the section.

The oblique lines  $CM, CM, CA$ , are equal, being radii of the sphere; hence they are equally distant from the perpendicular  $CO$  (Book VI. Prop. V. Cor.); therefore all the lines  $OM, OM, OB$ , are equal; consequently the section  $AMB$  is a circle, whose centre is  $O$ .

*Cor. 1.* If the section passes through the centre of the sphere, its radius will be the radius of the sphere; hence all great circles are equal.

*Cor. 2.* Two great circles always bisect each other; for their common intersection, passing through the centre, is a diameter.

*Cor. 3.* Every great circle divides the sphere and its surface into two equal parts: for, if the two hemispheres were separated and afterwards placed on the common base, with their convexities turned the same way, the two surfaces would exactly coincide, no point of the one being nearer the centre than any point of the other.

*Cor. 4.* The centre of a small circle, and that of the sphere, are in the same straight line, perpendicular to the plane of the small circle.

*Cor. 5.* Small circles are the less the further they lie from the centre of the sphere; for the greater  $CO$  is, the less is the chord  $AB$ , the diameter of the small circle  $AMB$ .

*Cor. 6.* An arc of a great circle may always be made to pass through any two given points of the surface of the sphere; for the two given points, and the centre of the sphere make three points which determine the position of a plane. But if the two given points were at the extremities of a diameter, these two points and the centre would then lie in one straight line, and an infinite number of great circles might be made to pass through the two given points.

## PROPOSITION VIII. THEOREM.

*Every plane perpendicular to a radius at its extremity is tangent to the sphere.*

Let FAG be a plane perpendicular to the radius OA, at its extremity A. Any point M in this plane being assumed, and OM, AM, being drawn, the angle OAM will be a right angle, and hence the distance OM will be greater than OA. Hence the point M lies without the sphere; and as the same can be shown for every other point of the plane FAG, this plane can have no point but A common to it and the surface of the sphere; hence it is a tangent plane (Def. 12.)

*Scholium.* In the same way it may be shown, that two spheres have but one point in common, and therefore touch each other, when the distance between their centres is equal to the sum, or the difference of their radii; in which case, the centres and the point of contact lie in the same straight line.

## PROPOSITION IX. LEMMA.

*If a regular semi-polygon be revolved about a line passing through the centre and the vertices of two opposite angles, the surface described by its perimeter will be equal to the axis multiplied by the circumference of the inscribed circle.*

Let the regular semi-polygon ABCDEF, be revolved about the line AF as an axis: then will the surface described by its perimeter be equal to AF multiplied by the circumference of the inscribed circle.

From E and D, the extremities of one of the equal sides, let fall the perpendiculars EH, DI, on the axis AF, and from the centre O draw ON perpendicular to the side DE: ON will be the radius of the inscribed circle (Book V. Prop. II.). Now, the surface described in the revolution by any one side of the regular polygon, as DE, has

been shown to be equal to  $DE \times \text{circ. NM}$  (Prop. IV. Sch.). But since the triangles EDK, ONM, are similar (Book IV. Prop. XXI.),  $ED : EK$  or  $HI : : ON : NM$ , or as  $\text{circ. ON} . \text{circ. NM}$ ; hence

$$ED \times \text{circ. NM} = HI \times \text{circ. ON};$$

and since the same may be shown for each of the other sides it is plain that the surface described by the entire perimeter is equal to

$$(FH + HI + IP + PQ + QA) \times \text{circ. ON} = AF \times \text{circ. ON}.$$

*Cor.* The surface described by any portion of the perimeter, as EDC, is equal to the distance between the two perpendiculars let fall from its extremities on the axis, multiplied by the circumference of the inscribed circle. For, the surface described by DE is equal to  $HI \times \text{circ. ON}$ , and the surface described by DC is equal to  $IP \times \text{circ. ON}$ : hence the surface described by  $ED + DC$ , is equal to  $(HI + IP) \times \text{circ. ON}$ , or equal to  $HP \times \text{circ. ON}$ .

#### PROPOSITION X. THEOREM.

*The surface of a sphere is equal to the product of its diameter by the circumference of a great circle.*

Let ABCDE be a semicircle. Inscribe in it any regular semi-polygon, and from the centre O draw OF perpendicular to one of the sides.

Let the semicircle and the semi-polygon be revolved about the axis AE: the semicircumference ABCDE will describe the surface of a sphere (Def. 8.); and the perimeter of the semi-polygon will describe a surface which has for its measure  $AE \times \text{circ. OF}$  (Prop. IX.), and this will be true whatever be the number of sides of the polygon. But if the number of sides of the polygon be indefinitely increased, its perimeter will coincide with the circumference ABCDE, the perpendicular OF will become equal to OE, and the surface described by the perimeter of the semi-polygon will then be the same as that described by the semicircumference ABCDE. Hence the surface of the sphere is equal to  $AE \times \text{circ. OE}$ .

*Cor.* Since the area of a great circle is equal to the product of its circumference by half the radius, or one fourth of the

diameter (Book V. Prop. XII.), it follows that *the surface of a sphere is equal to four of its great circles*: that is, equal to  $4\pi.OA^2$  (Book V. Prop. XII. Cor. 2.).

*Scholium 1. The surface of a zone is equal to its altitude multiplied by the circumference of a great circle.*

For, the surface described by any portion of the perimeter of the inscribed polygon, as  $BC + CD$ , is equal to  $EH \times \text{circ. OF}$  (Prop. IX. Cor.). But when the number of sides of the polygon is indefinitely increased,  $BC + CD$ , becomes the arc  $BCD$ ,  $OF$  becomes equal to  $OA$ , and the surface described by  $BC + CD$ , becomes the surface of the zone described by the arc  $BCD$ : hence the surface of the zone is equal to  $EH \times \text{circ. OA}$ .

*Scholium 2. When the zone has but one base, as the zone described by the arc ABCD, its surface will still be equal to the altitude AE multiplied by the circumference of a great circle.*

*Scholium 3. Two zones, taken in the same sphere or in equal spheres, are to each other as their altitudes; and any zone is to the surface of the sphere as the altitude of the zone is to the diameter of the sphere.*

#### PROPOSITION XI. LEMMA.

*If a triangle and a rectangle, having the same base and the same altitude, turn together about the common base, the solid described by the triangle will be a third of the cylinder described by the rectangle.*

Let  $ACB$  be the triangle, and  $BE$  the rectangle.

On the axis, let fall the perpendicular  $AD$ : the cone described by the triangle  $ABD$  is the third part of the cylinder described by the rectangle  $AFBD$  (Prop. V. Cor.); also the cone described by the triangle  $ADC$  is the third part of the cylinder described by the rectangle  $ADCE$ ; hence the sum of the two

cones, or the solid described by  $ABC$ , is the third part of the two cylinders taken together, or of the cylinder described by the rectangle  $BCEF$ .

If the perpendicular  $AD$  falls without the triangle; the solid described by  $ABC$  will, in that case, be the difference of the two cones described by  $ABD$  and  $ACD$ ; but at the same time, the cylinder described by  $BCEF$  will be the difference of the two cylinders described by  $AFBD$  and  $AECD$ . Hence the solid, described by the revolution of the triangle, will still be a third part of the cylinder described by the revolution of the rectangle having the same base and the same altitude.

*Scholium.* The circle of which  $AD$  is radius, has for its measure  $\pi \times AD^2$ ; hence  $\pi \times AD^2 \times BC$  measures the cylinder described by  $BCEF$ , and  $\frac{1}{3}\pi \times AD^2 \times BC$  measures the solid described by the triangle  $ABC$ .

#### PROPOSITION XII. LEMMA.

*If a triangle be revolved about a line drawn at pleasure through its vertex, the solid described by the triangle will have for its measure, the area of the triangle multiplied by two thirds of the circumference traced by the middle point of the base.*

Let  $CAB$  be the triangle, and  $CD$  the line about which it revolves.

Produce the side  $AB$  till it meets the axis  $CD$  in  $D$ ; from the points  $A$  and  $B$ , draw  $AM$ ,  $BN$ , perpendicular to the axis, and  $CP$  perpendicular to  $DA$  produced.

The solid described by the triangle  $CAD$  is measured by  $\frac{1}{3}\pi \times AM^2 \times CD$  (Prop. XI. Sch.); the solid described by the triangle  $CBD$  is measured by  $\frac{1}{3}\pi \times BN^2 \times CD$ ; hence the difference of those solids, or the solid described by  $ABC$ , will have for its measure  $\frac{1}{3}\pi(AM^2 - BN^2) \times CD$ .

To this expression another form may be given. From  $I$ , the middle point of  $AB$ , draw  $IK$  perpendicular to  $CD$ ; and through  $B$ , draw  $BO$  parallel to  $CD$ : we shall have  $AM + BN = 2IK$  (Book IV. Prop. VII.); and  $AM - BN = AO$ ; hence  $(AM + BN) \times (AM - BN)$ , or  $AM^2 - BN^2 = 2IK \times AO$  (Book IV. Prop. X.). Hence the measure of the solid in question is expressed by

$$\frac{2}{3}\pi \times IK \times AO \times CD.$$

But CP being drawn perpendicular to AB, the triangles ABO DCP will be similar, and give the proportion

$$AO : CP :: AB : CD ;$$

hence

$$AO \times CD = CP \times AB ;$$

but  $CP \times AB$  is double the area of the triangle ABC ; hence we have

$$AO \times CD = 2ABC ;$$

hence the solid described by the triangle ABC is also measured by  $\frac{4}{3}\pi \times ABC \times IK$ , or which is the same thing, by  $ABC \times \frac{2}{3} \text{circ. IK}$ , circ. IK being equal to  $2\pi \times IK$ .

Hence the solid described by the revolution of the triangle ABC, has for its measure the area of this triangle multiplied by two thirds of the circumference traced by I, the middle point of the base.

*Cor.* If the side  $AC = CB$ , the line CI will be perpendicular to AB, the area ABC will be equal to  $AB \times \frac{1}{2}CI$ , and the solidity  $\frac{4}{3}\pi \times ABC \times IK$  will become  $\frac{2}{3}\pi \times AB \times IK \times CI$ . But the triangles ABO, CIK, are similar, and give the proportion  $AB : BO$  or  $MN :: CI : IK$  ; hence  $AB \times IK = MN \times CI$  ; hence the

solid described by the isosceles triangle ABC will have for its measure  $\frac{2}{3}\pi \times CI^2 \times MN$  : that is, equal to two thirds of  $\pi$  into the square of the perpendicular let fall on the base, into the distance between the two perpendiculars let fall on the axis.

*Scholium.* The general solution appears to include the supposition that AB produced will meet the axis ; but the results would be equally true, though AB were parallel to the axis.

Thus, the cylinder described by AMNB is equal to  $\pi \cdot AM^2 \cdot MN$  ; the cone described by ACM is equal to  $\frac{1}{3}\pi \cdot AM^2 \cdot CM$ , and the cone described by BCN to  $\frac{1}{3}\pi \cdot AM^2 \cdot CN$ . Add the first two solids and take away the third ; we shall have the solid described by ABC equal to  $\pi \cdot AM^2 \cdot$

$(MN + \frac{1}{3}CM - \frac{1}{3}CN)$  : and since  $CN - CM = MN$ , this expression is reducible to  $\pi \cdot AM^2 \cdot \frac{2}{3}MN$ , or  $\frac{2}{3}\pi \cdot CP^2 \cdot MN$  ; which agrees with the conclusion found above.

## PROPOSITION XIII. LEMMA.

If a regular semi-polygon be revolved about a line passing through the centre and the vertices of two opposite angles, the solid described will be equivalent to a cone, having for its base the inscribed circle, and for its altitude twice the axis about which the semi-polygon is revolved.

Let the semi-polygon FABG be revolved about FG : then, if OI be the radius of the inscribed circle, the solid described will be measured by  $\frac{1}{3} \text{area } OI \times 2FG$ .

For, since the polygon is regular, the triangles OFA, OAB, OBC, &c. are equal and isosceles, and all the perpendiculars let fall from O on the bases FA, AB, &c. will be equal to OI, the radius of the inscribed circle.

Now, the solid described by OAB is measured by  $\frac{2}{3}\pi OI^2 + MN$  (Prop. XII. Cor.) ; the solid described by the triangle OFA has for its measure  $\frac{2}{3}\pi OI^2 \times FM$ , the solid described by the triangle OBC, has for its measure  $\frac{2}{3}\pi OI^2 \times NO$ , and since the same may be shown for the solid described by each of the other triangles, it follows that the entire solid described by the semi-polygon is measured by  $\frac{2}{3}\pi OI^2 \cdot (FM + MN + NO + OQ + QG)$ , or  $\frac{2}{3}\pi OI^2 \times FG$  ; which is also equal to  $\frac{1}{3}\pi OI^2 \times 2FG$ . But  $\pi \cdot OI^2$  is the area of the inscribed circle (Book V. Prop. XII. Cor. 2.) : hence the solidity is equivalent to a cone whose base is *area* OI, and altitude  $2FG$ .

## PROPOSITION XIV. THEOREM.

The solidity of a sphere is equal to its surface multiplied by a third of its radius.

Inscribe in the semicircle  $ABCDE$  a regular semi-polygon, having any number of sides, and let  $OI$  be the radius of the circle inscribed in the polygon.

If the semicircle and semi-polygon be revolved about  $EA$ , the semicircle will describe a sphere, and the semi-polygon a solid which has for its measure  $\frac{2}{3}\pi OI^2 \times EA$  (Prop. XIII.); and this will be true whatever be the number of sides of the polygon. But if the number of sides of the polygon be indefinitely increased, the semi-polygon will become the semicircle,  $OI$  will become equal to  $OA$ , and the solid described by the semi-polygon will become the sphere: hence the solidity of the sphere is equal to  $\frac{2}{3}\pi OA^2 \times EA$ , or by substituting  $2OA$  for  $EA$ , it becomes  $\frac{4}{3}\pi \cdot OA^2 \times OA$ , which is also equal to  $4\pi OA^2 \times \frac{1}{3}OA$ . But  $4\pi \cdot OA^2$  is equal to the surface of the sphere (Prop. X. Cor.): hence the solidity of a sphere is equal to its surface multiplied by a third of its radius.

*Scholium 1. The solidity of every spherical sector is equal to the zone which forms its base, multiplied by a third of the radius.*

For, the solid described by any portion of the regular polygon, as the isosceles triangle  $OAB$ , is measured by  $\frac{2}{3}\pi OI^2 \times AF$  (Prop. XII. Cor.); and when the polygon becomes the circle, the portion  $OAB$  becomes the sector  $AOB$ ,  $OI$  becomes equal to  $OA$ , and the solid described becomes a spherical sector. But its measure then becomes equal to  $\frac{2}{3}\pi \cdot AO^2 \times AF$ , which is equal to  $2\pi \cdot AO \times AF \times \frac{1}{3}AO$ . But  $2\pi \cdot AO$  is the circumference of a great circle of the sphere (Book V. Prop. XII. Cor. 2.), which being multiplied by  $AF$  gives the surface of the zone which forms the base of the sector (Prop. X. Sch. 1.): and the proof is equally applicable to the spherical sector described by the circular sector  $BOC$ : hence, the solidity of the spherical sector is equal to the zone which forms its base, multiplied by a third of the radius.

*Scholium 2. Since the surface of a sphere whose radius is  $R$ , is expressed by  $4\pi R^2$  (Prop. X. Cor.), it follows that the surfaces of spheres are to each other as the squares of their radii; and since their solidities are as their surfaces multiplied by their radii, it follows that the solidities of spheres are to each other as the cubes of their radii, or as the cubes of their diameters.*

*Scholium 3.* Let  $R$  be the radius of a sphere; its surface will be expressed by  $4\pi R^2$ , and its solidity by  $4\pi R^2 \times \frac{1}{3}R$ , or  $\frac{4}{3}\pi R^3$ . If the diameter is called  $D$ , we shall have  $R = \frac{1}{2}D$ , and  $R^3 = \frac{1}{8}D^3$ : hence the solidity of the sphere may likewise be expressed by

$$\frac{4}{3}\pi \times \frac{1}{8}D^3 = \frac{1}{6}\pi D^3.$$

PROPOSITION XV. THEOREM.

*The surface of a sphere is to the whole surface of the circumscribed cylinder, including its bases, as 2 is to 3: and the solidities of these two bodies are to each other in the same ratio.*

Let  $MPNQ$  be a great circle of the sphere;  $ABCD$  the circumscribed square: if the semicircle  $PMQ$  and the half square  $PADQ$  are at the same time made to revolve about the diameter  $PQ$ , the semicircle will generate the sphere, while the half square will generate the cylinder circumscribed about that sphere.

The altitude  $AD$  of the cylinder is equal to the diameter  $PQ$ ; the base of the cylinder is equal to the great circle, since its diameter  $AB$  is equal to  $MN$ ; hence, the convex surface of the cylinder is equal to the circumference of the great circle multiplied by its diameter (Prop. 1.). This measure is the same as that of the surface of the sphere (Prop. X.): hence *the surface of the sphere is equal to the convex surface of the circumscribed cylinder.*

But the surface of the sphere is equal to four great circles; hence the convex surface of the cylinder is also equal to four great circles: and adding the two bases, each equal to a great circle, the total surface of the circumscribed cylinder will be equal to six great circles; hence the surface of the sphere is to the total surface of the circumscribed cylinder as 4 is to 6, or as 2 is to 3; which was the first branch of the Proposition.

In the next place, since the base of the circumscribed cylinder is equal to a great circle, and its altitude to the diameter, the solidity of the cylinder will be equal to a great circle multiplied by its diameter (Prop. II.). But the solidity of the sphere is equal to four great circles multiplied by a third of the radius (Prop. XIV.); in other terms, to one great circle multiplied by  $\frac{4}{3}$  of the radius, or by  $\frac{2}{3}$  of the diameter; hence the sphere is to the circumscribed cylinder as 2 to 3, and consequently the solidities of these two bodies are as their surfacer

*Scholium.* Conceive a polyedron, all of whose faces touch the sphere; this polyedron may be considered as formed of pyramids, each having for its vertex the centre of the sphere, and for its base one of the polyedron's faces. Now it is evident that all these pyramids will have the radius of the sphere for their common altitude; so that each pyramid will be equal to one face of the polyedron multiplied by a third of the radius: hence the whole polyedron will be equal to its surface multiplied by a third of the radius of the inscribed sphere.

It is therefore manifest, that the solidities of polyedrons circumscribed about the sphere are to each other as the surfaces of those polyedrons. Thus the property, which we have shown to be true with regard to the circumscribed cylinder, is also true with regard to an infinite number of other bodies.

We might likewise have observed that the surfaces of polygons, circumscribed about the circle, are to each other as their perimeters.

#### PROPOSITION XVI. PROBLEM.

*If a circular segment be supposed to make a revolution about a diameter exterior to it, required the value of the solid which it describes.*

Let the segment BMD revolve about AC.

On the axis, let fall the perpendiculars BE, DF; from the centre C, draw CI perpendicular to the chord BD; also draw the radii CB, CD.

The solid described by the sector BCD is measured by  $\frac{2}{3}\pi \cdot CB^2 \cdot EF$  (Prop. XIV. Sch. 1). But the solid described by the isosceles triangle DCB has for its measure  $\frac{2}{3}\pi \cdot CI^2 \cdot EF$  (Prop. XII. Cor.); hence the solid described by the segment BMD  $= \frac{2}{3}\pi \cdot EF \cdot (CB^2 - CI^2)$ . Now, in the right-angled triangle CBI, we have  $CB^2 - CI^2 = BI^2 = \frac{1}{4}BD^2$ ; hence the solid described by the segment BMD will have for its measure  $\frac{2}{3}\pi \cdot EF \cdot \frac{1}{4}BD^2$ , or  $\frac{1}{6}\pi \cdot BD^2 \cdot EF$ : that is *one sixth of  $\pi$  into the square of the chord, into the distance between the two perpendiculars let fall from the extremities of the arc on the axis.*

*Scholium.* The solid described by the segment BMD is to the sphere which has BD for its diameter, as  $\frac{1}{6}\pi \cdot BD^2 \cdot EF$  is to  $\frac{1}{6}\pi \cdot BD^3$ , or as EF to BD.

## PROPOSITION XVII. THEOREM.

*Every segment of a sphere is measured by the half sum of its bases multiplied by its altitude, plus the solidity of a sphere whose diameter is this same altitude.*

Let BE, DF, be the radii of the two bases of the segment, EF its altitude, the segment being described by the revolution of the circular space BMDFE about the axis FE. The solid described by the segment BMD is equal to  $\frac{1}{6}\pi.BD^2.EF$  (Prop. XVI.) ; and the truncated cone described by the trapezoid BDFE is equal to  $\frac{1}{3}\pi.EF.(BE^2 + DF^2 + BE.DF)$  (Prop. VI.); hence the segment of the sphere, which is the sum of those two solids, must be equal to  $\frac{1}{6}\pi.EF.(2BE^2 + 2DF^2 + 2BE.DF + BD^2)$  But, drawing BO parallel to EF, we shall have  $DO = DF - BE$ , hence  $DO^2 = DF^2 - 2DF.BE + BE^2$  (Book IV. Prop. IX.) ; and consequently  $BD^2 = BO^2 + DO^2 = EF^2 + DF^2 - 2DF.BE + BE^2$ . Put this value in place of  $BD^2$  in the expression for the value of the segment, omitting the parts which destroy each other ; we shall obtain for the solidity of the segment,

$\frac{1}{6}\pi.EF.(3BE^2 + 3DF^2 + EF^2)$ ,  
an expression which may be decomposed into two parts ; the one  $\frac{1}{6}\pi.EF.(3BE^2 + 3DF^2)$ , or  $EF.\left(\frac{\pi.BE^2 + \pi.DF^2}{2}\right)$  being the half sum of the bases multiplied by the altitude ; while the other  $\frac{1}{6}\pi.EF^3$  represents the sphere of which EF is the diameter (Prop. XIV. Sch.) : hence every segment of a sphere, &c.

*Cor.* If either of the bases is nothing, the segment in question becomes a spherical segment with a single base ; hence *any spherical segment, with a single base, is equivalent to half the cylinder having the same base and the same altitude, plus the sphere of which this altitude is the diameter.*

*General Scholium.*

Let R be the radius of a cylinder's base, H its altitude : the solidity of the cylinder will be  $\pi R^2 \times H$ , or  $\pi R^2 H$ .

Let R be the radius of a cone's base, H its altitude : the solidity of the cone will be  $\pi R^2 \times \frac{1}{3}H$ , or  $\frac{1}{3}\pi R^2 H$ .

Let A and B be the radii of the bases of a truncated cone,

If its altitude : the solidity of the truncated cone will be  $\frac{1}{3}\pi.H.(A^2 + B^2 + AB)$ .

Let  $R$  be the radius of a sphere ; its solidity will be  $\frac{4}{3}\pi R^3$ .

Let  $R$  be the radius of a spherical sector,  $H$  the altitude of the zone, which forms its base : the solidity of the sector will be  $\frac{2}{3}\pi R^2 H$ .

Let  $P$  and  $Q$  be the two bases of a spherical segment,  $H$  its altitude : the solidity of the segment will be  $\frac{P+Q}{2}.H + \frac{1}{6}\pi.H^3$ .

If the spherical segment has but one base, the other being nothing, its solidity will be  $\frac{1}{2}PH + \frac{1}{6}\pi H^3$ .

## BOOK IX.

### OF SPHERICAL TRIANGLES AND SPHERICAL POLYGONS.

#### *Definitions.*

1. A *spherical triangle* is a portion of the surface of a sphere, bounded by three arcs of great circles.

These arcs are named the *sides* of the triangle, and are always supposed to be each less than a semi-circumference. The angles, which their planes form with each other, are the angles of the triangle.

2. A spherical triangle takes the name of *right-angled*, *isosceles*, *equilateral*, in the same cases as a rectilineal triangle.

3. A *spherical polygon* is a portion of the surface of a sphere terminated by several arcs of great circles.

4. A *lune* is that portion of the surface of a sphere, which is included between two great semi-circles meeting in a common diameter.

5. A *spherical wedge* or *ungula* is that portion of the solid sphere, which is included between the same great semi-circles, and has the lune for its base.

6. A *spherical pyramid* is a portion of the solid sphere, included between the planes of a solid angle whose vertex is the centre. The *base* of the pyramid is the spherical polygon intercepted by the same planes.

7. The *pole of a circle* of a sphere is a point in the surface equally distant from all the points in the circumference of this circle. It will be shown (Prop. V.) that every circle, great or small, has always two poles.

## PROPOSITION I. THEOREM.

*In every spherical triangle, any side is less than the sum of the other two.*

Let  $O$  be the centre of the sphere, and  $ACB$  the triangle; draw the radii  $OA, OB, OC$ . Imagine the planes  $AOB, AOC, COB$ , to be drawn; these planes will form a solid angle at the centre  $O$ ; and the angles  $AOB, AOC, COB$ , will be measured by  $AB, AC, BC$ , the sides of the spherical triangle. But each of the three plane angles forming a solid angle is less than the sum of the other two (Book VI. Prop. XIX.); hence any side of the triangle  $ABC$  is less than the sum of the other two.

## PROPOSITION II. THEOREM.

*The shortest path from one point to another, on the surface of a sphere, is the arc of the great circle which joins the two given points.*

Let  $ANB$  be the arc of a great circle which joins the points  $A$  and  $B$ ; then will it be the shortest path between them.

1st.. If two points  $N$  and  $B$ , be taken on the arc of a great circle, at unequal distances from the point  $A$ , the shortest distance from  $B$  to  $A$  will be greater than the shortest distance from  $N$  to  $A$ .

For, about  $A$  as a pole describe a circumference  $CNP$ . Now, the line of shortest distance from  $B$  to  $A$  must cross this circumference at some point as  $P$ : But the shortest distance from  $P$  to  $A$  whether it be the arc of a great circle or any other line, is equal to the shortest distance from  $N$  to  $A$ ; for, by passing the arc of a great circle through  $P$  and  $A$ , and revolving it about the diameter passing through  $A$ , the point  $P$  may be made to coincide with  $N$ , when the shortest distance from  $P$  to  $A$  will coincide with the shortest distance from  $N$  to  $A$ : hence, the shortest distance from  $B$  to  $A$ , will be greater than the shortest distance from  $N$  to  $A$ , by the shortest distance from  $B$  to  $P$ .

If the point  $B$  be taken without the arc  $AN$ , still making  $AB$  greater than  $AN$ , it may be proved in a manner entirely similar to the above, that the shortest distance from  $B$  to  $A$  will be greater than the shortest distance from  $N$  to  $A$ .

If now, there be a shorter path between the points  $B$  and  $A$ , than the arc  $BDA$  of a great circle, let  $M$  be a point of the short-

est distance possible; then through  $M$  draw  $MA$ ,  $MB$ , arcs of great circles, and take  $BD$  equal to  $BM$ . By the last theorem,  $BDA < BM + MA$ ; take  $BD = BM$  from each, and there will remain  $AD < AM$ . Now, since  $BM = BD$ , the shortest path from  $B$  to  $M$  is equal to the shortest path from  $B$  to  $D$ : hence if we suppose two paths from  $B$  to  $A$ , one passing through  $M$  and the other through  $D$ , they will have an equal part in each; viz. the part from  $B$  to  $M$  equal to the part from  $B$  to  $D$ .

But by hypothesis, the path through  $M$  is the shortest path from  $B$  to  $A$ : hence the shortest path from  $M$  to  $A$  must be less than the shortest path from  $D$  to  $A$ , whereas it is greater since the arc  $MA$  is greater than  $DA$ : hence, no point of the shortest distance between  $B$  and  $A$  can lie out of the arc of the great circle  $BDA$ .

### PROPOSITION III. THEOREM.

*The sum of the three sides of a spherical triangle is less than the circumference of a great circle.*

Let  $ABC$  be any spherical triangle; produce the sides  $AB$ ,  $AC$ , till they meet again in  $D$ . The arcs  $ABD$ ,  $ACD$ , will be semicircumferences, since two great circles always bisect each other (Book VIII. Prop. VII. Cor. 2.). But in the triangle  $BCD$ , we have the side  $BC < BD + CD$  (Prop I.); add  $AB + AC$  to both; we shall have  $AB + AC + BC < ABD + ACD$ , that is to say, less than a circumference.

### PROPOSITION IV. THEOREM

*The sum of all the sides of any spherical polygon is less than the circumference of a great circle.*

Take the pentagon  $ABCDE$ , for example. Produce the sides  $AB$ ,  $DC$ , till they meet in  $F$ ; then since  $BC$  is less than  $BF + CF$ , the perimeter of the pentagon  $ABCDE$  will be less than that of the quadrilateral  $AEDF$ .

Again, produce the sides  $AE$ ,  $FD$ , till they meet in  $G$ ; we shall have  $ED < EG + DG$ ; hence the perimeter of the quadrilateral  $AEDF$  is less than that of the triangle  $AFG$ ; which last is itself less than the circumference of a great circle; hence, for a still stronger reason, the perimeter of the polygon  $ABCDE$  is less than this same circumference.

*Scholium.* This proposition is fundamentally the same as (Book VI. Prop. XX.); for, O being the centre of the sphere, a solid angle may be conceived as formed at O by the plane angles AOB, BOC, COD, &c., and the sum of these angles must be less than four right angles; which is exactly the proposition here proved. The demonstration here given is different from that of Book VI. Prop. XX.; both, however, suppose that the polygon ABCDE is convex, or that no side produced will cut the figure.

### PROPOSITION V. THEOREM.

*The poles of a great circle of a sphere, are the extremities of that diameter of the sphere which is perpendicular to the circle; and these extremities are also the poles of all small circles parallel to it.*

Let ED be perpendicular to the great circle AMB; then will E and D be its poles; as also the poles of the parallel small circles HPI, FNG.

For, DC being perpendicular to the plane AMB, is perpendicular to all the straight lines CA, CM, CB, &c. drawn through its foot in this plane; hence all the arcs DA, DM, DB, &c. are quarters of the circumference. So likewise are all the arcs EA, EM, EB, &c.; hence the points D and E are each equally distant from all the points of the circumference AMB; hence, they are the poles of that circumference (Def. 7.).

Again, the radius DC, perpendicular to the plane AMB, is perpendicular to its parallel FNG; hence, it passes through O the centre of the circle FNG (Book VIII. Prop. VII. Cor. 4.); hence, if the oblique lines DF, DN, DG, be drawn, these oblique lines will diverge equally from the perpendicular DO, and will themselves be equal. But, the chords being equal,

the arcs are equal; hence the point  $D$  is the pole of the small circle  $FNG$ ; and for like reasons, the point  $E$  is the other pole.

*Cor. 1.* Every arc  $DM$ , drawn from a point in the arc of a great circle  $AMB$  to its pole, is a quarter of the circumference, which for the sake of brevity, is usually named a *quadrant*: and this quadrant at the same time makes a right angle with the arc  $AM$ . For, the line  $DC$  being perpendicular to the plane  $AMC$ , every plane  $DME$ , passing through the line  $DC$  is perpendicular to the plane  $AMC$  (Book VI. Prop. XVI.); hence, the angle of these planes, or the angle  $AMD$ , is a right angle.

*Cor. 2.* To find the pole of a given arc  $AM$ , draw the indefinite arc  $MD$  perpendicular to  $AM$ ; take  $MD$  equal to a quadrant; the point  $D$  will be one of the poles of the arc  $AM$ : or thus, at the two points  $A$  and  $M$ , draw the arcs  $AD$  and  $MD$  perpendicular to  $AM$ ; their point of intersection  $D$  will be the pole required.

*Cor. 3.* Conversely, if the distance of the point  $D$  from each of the points  $A$  and  $M$  is equal to a quadrant, the point  $D$  will be the pole of the arc  $AM$ , and also the angles  $DAM$ ,  $AMD$ , will be right angles.

For, let  $C$  be the centre of the sphere; and draw the radii  $CA$ ,  $CD$ ,  $CM$ . Since the angles  $ACD$ ,  $MCD$ , are right angles, the line  $CD$  is perpendicular to the two straight lines  $CA$ ,  $CM$ ; hence it is perpendicular to their plane (Book VI. Prop. IV.); hence the point  $D$  is the pole of the arc  $AM$ ; and consequently the angles  $DAM$ ,  $AMD$ , are right angles.

*Scholium.* The properties of these poles enable us to describe arcs of a circle on the surface of a sphere, with the same facility as on a plane surface. It is evident, for instance, that by turning the arc  $DF$ , or any other line extending to the same distance, round the point  $D$ , the extremity  $F$  will describe the small circle  $FNG$ ; and by turning the quadrant  $DFA$  round

the point D, its extremity A will describe the arc of the great circle AMB.

If the arc AM were required to be produced, and nothing were given but the points A and M through which it was to pass, we should first have to determine the pole D, by the intersection of two arcs described from the points A and M as centres, with a distance equal to a quadrant; the pole D being found, we might describe the arc AM and its prolongation, from D as a centre, and with the same distance as before.

In fine, if it be required from a given point P, to let fall a perpendicular on the given arc AM; find a point on the arc AM at a quadrant's distance from the point P, which is done by describing an arc with the point P as a pole, intersecting AM in S: S will be the point required, and is the pole with which a perpendicular to AM may be described passing through the point P.

#### PROPOSITION VI. THEOREM.

*The angle formed by two arcs of great circles, is equal to the angle formed by the tangents of these arcs at their point of intersection, and is measured by the arc described from this point of intersection, as a pole, and limited by the sides, produced if necessary.*

Let the angle BAC be formed by the two arcs AB, AC; then will it be equal to the angle FAG formed by the tangents AF, AG, and be measured by the arc DE, described about A as a pole.

For the tangent AF, drawn in the plane of the arc AB, is perpendicular to the radius AO; and the tangent AG, drawn in the plane of the arc AC, is perpendicular to the same radius AO. Hence the angle FAG is equal to the angle contained by the planes ABO, OAC (Book VI. Def. 4.); which is that of the arcs AB, AC, and is called the angle BAC.

In like manner, if the arcs AD and AE are both quadrants, the lines OD, OE, will be perpendicular to OA, and the angle DOE will still be equal to the angle of the planes AOD, AOE: hence the arc DE is the measure of the angle contained by these planes, or of the angle CAB.

*Cor.* The angles of spherical triangles may be compared together, by means of the arcs of great circles described from their vertices as poles and included between their sides: hence it is easy to make an angle of this kind equal to a given angle.

*Scholium.* Vertical angles, such as  $\angle ACO$  and  $\angle BCN$  are equal; for either of them is still the angle formed by the two planes  $ACB$ ,  $OCN$ .

It is farther evident, that, in the intersection of two arcs  $ACB$ ,  $OCN$ , the two adjacent angles  $\angle ACO$ ,  $\angle OCB$ , taken together, are equal to two right angles.

### PROPOSITION VII. THEOREM.

*If from the vertices of the three angles of a spherical triangle, as poles, three arcs be described forming a second triangle, the vertices of the angles of this second triangle, will be respectively poles of the sides of the first.*

From the vertices  $A$ ,  $B$ ,  $C$ , as poles, let the arcs  $EF$ ,  $FD$ ,  $ED$ , be described, forming on the surface of the sphere, the triangle  $DFE$ ; then will the points  $D$ ,  $E$ , and  $F$ , be respectively poles of the sides  $BC$ ,  $AC$ ,  $AB$ .

For, the point  $A$  being the pole of the arc  $EF$ , the distance  $AE$  is a quadrant; the point  $C$  being the pole of the arc  $DE$ , the distance  $CE$  is likewise a quadrant: hence the point  $E$  is removed the length of a quadrant from each of the points  $A$  and  $C$ ; hence, it is the pole of the arc  $AC$  (Prop. V. Cor. 3.). It might be shown, by the same method, that  $D$  is the pole of the arc  $BC$ , and  $F$  that of the arc  $AB$ .

*Cor.* Hence the triangle  $ABC$  may be described by means of  $DEF$ , as  $DEF$  is described by means of  $ABC$ . Triangles so described are called *polar triangles*, or *supplemental triangles*.

PROPOSITION VIII. THEOREM.

*The same supposition continuing as in the last Proposition, each angle in one of the triangles, will be measured by a semicircumference, minus the side lying opposite to it in the other triangle.*

For, produce the sides AB, AC, if necessary, till they meet EF, in G and H. The point A being the pole of the arc GH, the angle A will be measured by that arc (Prop. VI.). But the arc EH is a quadrant, and likewise GF, E being the pole of AH, and F of AG; hence EH + GF is equal to a semicircumference. Now, EH + GF is the same as EF + GH; hence the arc GH, which measures the angle A, is equal to a semicircumference *minus* the side EF. In like manner, the angle B will be measured by  $\frac{1}{2}$  circ.—DF: the angle C, by  $\frac{1}{2}$  circ.—DE.

And this property must be reciprocal in the two triangles, since each of them is described in a similar manner by means of the other. Thus we shall find the angles D, E, F, of the triangle DEF to be measured respectively by  $\frac{1}{2}$  circ.—BC,  $\frac{1}{2}$  circ.—AC,  $\frac{1}{2}$  circ.—AB. Thus the angle D, for example, is measured by the arc MI; but MI + BC = MC + BI =  $\frac{1}{2}$  circ.; hence the arc MI, the measure of D, is equal to  $\frac{1}{2}$  circ.—BC: and so of all the rest.

*Scholium.* It must further be observed, that besides the triangle DEF, three others might be formed by the intersection of the three arcs DE, EF, DF. But the proposition immediately before us is applicable only to the central triangle, which is distinguished from the other three by the circumstance (see the last figure) that the two angles A and D lie on the same side of B', the two B and E on the same side of AC, and the two C and F on the same side of AB.

## PROPOSITION IX. THEOREM.

*If around the vertices of the two angles of a given spherical triangle, as poles, the circumferences of two circles be described which shall pass through the third angle of the triangle; if then, through the other point in which these circumferences intersect and the two first angles of the triangle, the arcs of great circles be drawn, the triangle thus formed will have all its parts equal to those of the given triangle.*

Let  $ABC$  be the given triangle,  $CED$ ,  $DFC$ , the arcs described about  $A$  and  $B$  as poles; then will the triangle  $ADB$  have all its parts equal to those of  $ABC$ .

For, by construction, the side  $AD = AC$ ,  $DB = BC$ , and  $AB$  is common; hence these two triangles have their sides equal, each to each. We are now to show, that the angles opposite these equal sides are also equal.

If the centre of the sphere is supposed to be at  $O$ , a solid angle may be conceived as formed at  $O$  by the three plane angles  $AOB$ ,  $AOC$ ,  $BOC$ ; likewise another solid angle may be conceived as formed by the three plane angles  $AOB$ ,  $AOD$ ,  $BOD$ . And because the sides of the triangle  $ABC$  are equal to those of the triangle  $ADB$ , the plane angles forming the one of these solid angles, must be equal to the plane angles forming the other, each to each. But in that case we have shown that the planes, in which the equal angles lie, are equally inclined to each other (Book VI. Prop. XXI.); hence all the angles of the spherical triangle  $DAB$  are respectively equal to those of the triangle  $CAB$ , namely,  $DAB = BAC$ ,  $DBA = ABC$ , and  $ADB = ACB$ ; hence the sides and the angles of the triangle  $ADB$  are equal to the sides and the angles of the triangle  $ACB$ .

*Scholium.* The equality of these triangles is not, however, an absolute equality, or one of superposition; for it would be impossible to apply them to each other exactly, unless they were isosceles. The equality meant here is what we have already named an equality by *symmetry*; therefore we shall call the triangles  $ACB$ ,  $ADB$ , *symmetrical triangles*.

## PROPOSITION X. THEOREM.

*Two triangles on the same sphere, or on equal spheres, are equal in all their parts, when two sides and the included angle of the one are equal to two sides and the included angle of the other, each to each.*

Suppose the side  $AB=EF$ , the side  $AC=EG$ , and the angle  $BAC=FEG$ ; then will the two triangles be equal in all their parts.

For, the triangle  $EFG$  may be placed on the triangle  $ABC$ , or on  $ABD$  symmetrical with  $ABC$ , just as two rectilineal triangles are placed upon each other, when they have an equal angle included between equal sides. Hence all the parts of the triangle  $EFG$  will be equal to all the parts of the triangle  $ABC$ ; that is, besides the three parts equal by hypothesis, we shall have the side  $BC=FG$ , the angle  $ABC=EFG$ , and the angle  $ACB=EGF$ .

## PROPOSITION XI. THEOREM.

*Two triangles on the same sphere, or on equal spheres, are equal in all their parts, when two angles and the included side of the one are equal to two angles and the included side of the other, each to each.*

For, one of these triangles, or the triangle symmetrical with it, may be placed on the other, as is done in the corresponding case of rectilineal triangles (Book I. Prop. VI.).

## PROPOSITION XII. THEOREM.

*If two triangles on the same sphere, or on equal spheres, have all their sides equal, each to each, their angles will likewise be equal, each to each, the equal angles lying opposite the equal sides.*

This truth is evident from Prop. IX, where it was shown, that with three given sides  $AB, AC, BC$ , there can only be two triangles  $ACB, ABD$ , differing as to the position of their parts, and equal as to the magnitude of those parts. Hence those two triangles, having all their sides respectively equal in both, must either be absolutely equal, or at least *symmetrically* so; in either of which cases, their corresponding angles must be equal, and lie opposite to equal sides.

PROPOSITION XIII. THEOREM.

*In every isosceles spherical triangle, the angles opposite the equal sides are equal; and conversely, if two angles of a spherical triangle are equal, the triangle is isosceles.*

*First.* Suppose the side  $AB=AC$ ; we shall have the angle  $C=B$ . For, if the arc  $AD$  be drawn from the vertex  $A$  to the middle point  $D$  of the base, the two triangles  $ABD, ACD$ , will have all the sides of the one respectively equal to the corresponding sides of the other, namely,  $AD$  common,  $BD=DC$ , and  $AB=AC$ : hence by the last Proposition, their angles will be equal; therefore,  $B=C$ .

*Secondly.* Suppose the angle  $B=C$ ; we shall have the side  $AC=AB$ . For, if not, let  $AB$  be the greater of the two; take  $BO=AC$ , and draw  $OC$ . The two sides  $BO, BC$ , are equal to the two  $AC, BC$ ; the angle  $OBC$ , contained by the first two is equal to  $ACB$  contained by the second two. Hence the two triangles  $BOC, ACB$ , have all their other parts equal (Prop. X.); hence the angle  $OCB=ABC$ : but by hypothesis, the angle  $ABC=ACB$ ; hence we have  $OCB=ACB$ , which is absurd; hence it is absurd to suppose  $AB$  different from  $AC$ ; hence the sides  $AB, AC$ , opposite to the equal angles  $B$  and  $C$ , are equal.

*Scholium.* The same demonstration proves the angle  $BAD=DAC$ , and the angle  $BDA=ADC$ . Hence the two last are right angles; hence *the arc drawn from the vertex of an isosceles spherical triangle to the middle of the base, is at right angles to that base, and bisects the vertical angle.*

## PROPOSITION XIV. THEOREM.

*In any spherical triangle, the greater side is opposite the greater angle ; and conversely, the greater angle is opposite the greater side.*

Let the angle  $A$  be greater than the angle  $B$ , then will  $BC$  be greater than  $AC$ ; and conversely, if  $BC$  is greater than  $AC$ , then will the angle  $A$  be greater than  $B$ .

*First.* Suppose the angle  $A > B$ ; make the angle  $BAD = B$ ; then we shall have  $AD = DB$  (Prop. XIII.): but  $AD + DC$  is greater than  $AC$ ; hence, putting  $DB$  in place of  $AD$ , we shall have  $DB + DC$ , or  $BC > AC$ .

*Secondly.* If we suppose  $BC > AC$ , the angle  $BAC$  will be greater than  $ABC$ . For, if  $BAC$  were equal to  $ABC$ , we should have  $BC = AC$ ; if  $BAC$  were less than  $ABC$ , we should then, as has just been shown, find  $BC < AC$ . Both these conclusions are false: hence the angle  $BAC$  is greater than  $ABC$ .

## PROPOSITION XV. THEOREM.

*If two triangles on the same sphere, or on equal spheres, are mutually equiangular, they will also be mutually equilateral.*

Let  $A$  and  $B$  be the two given triangles;  $P$  and  $Q$  their polar triangles. Since the angles are equal in the triangles  $A$  and  $B$ , the sides will be equal in their polar triangles  $P$  and  $Q$  (Prop. VIII.): but since the triangles  $P$  and  $Q$  are mutually equilateral, they must also be mutually equiangular (Prop. XII.); and lastly, the angles being equal in the triangles  $P$  and  $Q$ , it follows that the sides are equal in their polar triangles  $A$  and  $B$ . Hence the mutually equiangular triangles  $A$  and  $B$  are at the same time mutually equilateral.

*Scholium.* This proposition is not applicable to rectilinear triangles; in which equality among the angles indicates only proportionality among the sides. Nor is it difficult to account for the difference observable, in this respect, between spherical and rectilinear triangles. In the Proposition now before us,

as well as in the preceding ones, which treat of the comparison of triangles, it is expressly required that the arcs be traced on the same sphere, or on equal spheres. Now similar arcs are to each other as their radii; hence, on equal spheres, two triangles cannot be similar without being equal. Therefore it is not strange that equality among the angles should produce equality among the sides.

The case would be different, if the triangles were drawn upon unequal spheres; there, the angles being equal, the triangles would be similar, and the homologous sides would be to each other as the radii of their spheres.

#### PROPOSITION XVI. THEOREM.

*The sum of all the angles in any spherical triangle is less than six right angles, and greater than two.*

For, in the first place, every angle of a spherical triangle is less than two right angles: hence the sum of all the three is less than six right angles.

Secondly, the measure of each angle of a spherical triangle is equal to the semicircumference *minus* the corresponding side of the polar triangle (Prop. VIII.); hence the sum of all the three, is measured by the three semicircumferences *minus* the sum of all the sides of the polar triangle. Now this latter sum is less than a circumference (Prop. III.); therefore, taking it away from three semicircumferences, the remainder will be greater than one semicircumference, which is the measure of two right angles; hence, in the second place, the sum of all the angles of a spherical triangle is greater than two right angles.

*Cor. 1.* The sum of all the angles of a spherical triangle is not constant, like that of all the angles of a rectilineal triangle; it varies between two right angles and six, without ever arriving at either of these limits. Two given angles therefore do not serve to determine the third.

*Cor. 2.* A spherical triangle may have two, or even three of its angles right angles; also two, or even three of its angles obtuse.

*Cor. 3.* If the triangle  $ABC$  is *bi-rectangular*, in other words, has two right angles  $B$  and  $C$ , the vertex  $A$  will be the pole of the base  $BC$ ; and the sides  $AB$ ,  $AC$ , will be quadrants (Prop. V. Cor. 3.).

If the angle  $A$  is also a right angle, the triangle  $ABC$  will be *tri-rectangular*; its angles will all be right angles, and its sides quadrants. Two of the tri-rectangular triangles make half a hemisphere, four make a hemisphere, and the tri-rectangular triangle is obviously contained eight times in the surface of a sphere.

*Scholium.* In all the preceding observations, we have supposed, in conformity with (Def. 1.) that spherical triangles have always each of their sides less than a semicircumference; from which it follows that any one of their angles is always less than two right angles. For, if the side  $AB$  is less than a semicircumference, and  $AC$  is so likewise, both those arcs will require to be produced, before they can meet in  $D$ . Now the two angles  $ABC$ ,  $CBD$ , taken together, are equal to two right angles; hence the angle  $ABC$  itself, is less than two right angles.

We may observe, however, that some spherical triangles do exist, in which certain of the sides are greater than a semicircumference, and certain of the angles greater than two right angles. Thus, if the side  $AC$  is produced so as to form a whole circumference  $ACE$ , the part which remains, after subtracting the triangle  $ABC$  from the hemisphere, is a new triangle also designated by  $ABC$ , and having  $AB$ ,  $BC$ ,  $AEDC$  for its sides. Here, it is plain, the side  $AEDC$  is greater than the semicircumference  $AED$ ; and at the same time, the angle  $B$  opposite to it exceeds two right angles, by the quantity  $CBD$ .

The triangles whose sides and angles are so large, have been excluded by the Definition; but the only reason was, that the solution of them, or the determination of their parts, is always reducible to the solution of such triangles as are comprehended by the Definition. Indeed, it is evident enough, that if the sides and angles of the triangle  $ABC$  are known, it will be easy to discover the angles and sides of the triangle which bears the same name, and is the difference between a hemisphere and the former triangle.

## PROPOSITION XVII. THEOREM.

*The surface of a lune is to the surface of the sphere, as the angle of this lune, is to four right angles, or as the arc which measures that angle, is to the circumference.*

Let  $AMBN$  be a lune ; then will its surface be to the surface of the sphere as the angle  $NCM$  to four right angles, or as the arc  $NM$  to the circumference of a great circle.

Suppose, in the first place, the arc  $MN$  to be to the circumference  $MNPQ$  as some one rational number is to another, as 5 to 48, for example. The circumference  $MNPQ$  being divided into 48 equal parts,  $MN$  will contain 5 of them ; and if the pole  $A$  were joined with the several points of division, by as many quadrants, we should in the hemisphere  $AMNPQ$  have 48 triangles, all equal, because all their parts are equal. Hence the whole sphere must contain 96 of those partial triangles, the lune  $AMBNA$  will contain 10 of them ; hence the lune is to the sphere as 10 is to 96, or as 5 to 48, in other words, as the arc  $MN$  is to the circumference.

If the arc  $MN$  is not commensurable with the circumference, we may still show, by a mode of reasoning frequently exemplified already, that in that case also, the lune is to the sphere as  $MN$  is to the circumference.

*Cor. 1.* Two lunes are to each other as their respective angles.

*Cor. 2.* It was shown above, that the whole surface of the sphere is equal to eight tri-rectangular triangles (*Prop. XVI. Cor. 3.*) ; hence, if the area of one such triangle is represented by  $T$ , the surface of the whole sphere will be expressed by  $8T$ . This granted, if the right angle be assumed equal to 1, the surface of the lune whose angle is  $A$ , will be expressed by  $2A \times T$ . for,

$$4 : A :: 8T : 2A \times T$$

in which expression,  $A$  represents such a part of unity, as the angle of the lune is of one right angle.

*Scholium.* The spherical ungula, bounded by the planes  $AMB$ ,  $ANB$ , is to the whole solid sphere, as the angle  $A$  is to

four right angles. For, the lunes being equal, the spherical unguulas will also be equal; hence two spherical unguulas are to each other, as the angles formed by the planes which bound them.

PROPOSITION XVIII. THEOREM.

*Two symmetrical spherical triangles are equivalent.*

Let  $ABC, DEF$ , be two symmetrical triangles, that is to say, two triangles having their sides  $AB=DE$ ,  $AC=DF$ ,  $CB=EF$ , and yet incapable of coinciding with each other: we are to show that the surface  $ABC$  is equal to the surface  $DEF$ .

Let  $P$  be the pole of the small circle passing through the three points  $A, B, C$ ;\* from this point draw the equal arcs  $PA, PB, PC$  (Prop. V.); at the point  $F$ , make the angle  $DFQ=ACP$ , the arc  $FQ=CP$ ; and draw  $DQ, EQ$ .

The sides  $DF, FQ$ , are equal to the sides  $AC, CP$ ; the angle  $DFQ=ACP$ : hence the two triangles  $DFQ, ACP$  are equal in all their parts (Prop. X.); hence the side  $DQ=AP$ , and the angle  $DQF=APC$ .

In the proposed triangles  $DFE, ABC$ , the angles  $DFE, ACB$ , opposite to the equal sides  $DE, AB$ , being equal (Prop. XII.). if the angles  $DFQ, ACP$ , which are equal by construction, be taken away from them, there will remain the angle  $QFE$ , equal to  $PCB$ . Also the sides  $QF, FE$ , are equal to the sides  $PC, CB$ ; hence the two triangles  $FQE, CPB$ , are equal in all their parts; hence the side  $QE=PB$ , and the angle  $FQE=CPB$ .

Now, the triangles  $DFQ, ACP$ , which have their sides respectively equal, are at the same time isosceles, and capable of coinciding, when applied to each other; for having placed  $AC$  on its equal  $DF$ , the equal sides will fall on each other, and thus the two triangles will exactly coincide: hence they are equal; and the surface  $DQF=APC$ . For a like reason, the surface  $FQE=CPB$ , and the surface  $DQE=APB$ ; hence we

---

\* The circle which passes through the three points  $A, B, C$ , or which circumscribes the triangle  $ABC$ , can only be a small circle of the sphere; for if it were a great circle, the three sides  $AB, BC, AC$ , would lie in one plane, and the triangle  $ABC$  would be reduced to one of its sides.

have  $DQF + FQE - DQE = APC + CPB - APB$ , or  $DFE = ABC$ ; hence the two symmetrical triangles  $ABC, DEF$  are equal in surface.

*Scholium.* The poles  $P$  and  $Q$  might lie within triangles  $ABC, DEF$ : in which case it would be requisite to add the three triangles  $DQF, FQE, DQE$ , together, in order to make up the triangle  $DEF$ ; and in like manner, to add the three triangles  $APC, CPB, APB$ , together, in order to make up the triangle  $ABC$ : in all other respects, the demonstration and the result would still be the same.

#### PROPOSITION XIX. THEOREM.

*If the circumferences of two great circles intersect each other on the surface of a hemisphere, the sum of the opposite triangles thus formed, is equivalent to the surface of a lune whose angle is equal to the angle formed by the circles.*

Let the circumferences  $AOB, COD$ , intersect on the hemisphere  $OACBD$ ; then will the opposite triangles  $AOC, BOD$ , be equal to the lune whose angle is  $BOD$ .

For, producing the arcs  $OB, OD$ , on the other hemisphere, till they meet in  $N$ , the arc  $OBN$  will be a semi-circumference, and  $AOB$  one also; and taking  $OB$  from each, we shall have  $BN = AO$ .

For a like reason, we have  $DN = CO$ , and  $BD = AC$ . Hence, the two triangles  $AOC, BDN$ , have their three sides respectively equal; they are therefore symmetrical; hence they are equal in surface (Prop. XVIII.): but the sum of the triangles  $BDN, BOD$ , is equivalent to the lune  $OBND$ , whose angle is  $BOD$ : hence,  $AOC + BOD$  is equivalent to the lune whose angle is  $BOD$ .

*Scholium.* It is likewise evident that the two spherical pyramids, which have the triangles  $AOC, BOD$ , for bases, are together equivalent to the spherical ungula whose angle is  $BOD$ .

## PROPOSITION XX. THEOREM.

*The surface of a spherical triangle is measured by the excess of the sum of its three angles above two right angles, multiplied by the tri-rectangular triangle.*

Let  $ABC$  be the proposed triangle: produce its sides till they meet the great circle  $DEFG$  drawn at pleasure without the triangle. By the last Theorem, the two triangles  $ADE$ ,  $AGH$ , are together equivalent to the lune whose angle is  $A$ , and which is measured by  $2A.T$  (Prop. XVII. Cor. 2.). Hence we have  $ADE + AGH = 2A.T$ ; and for a like reason,  $BGF + BID = 2B.T$ , and  $CIH + CFE = 2C.T$ . But the sum of these six triangles exceeds the hemisphere by twice the triangle  $ABC$ , and the hemisphere is represented by  $4T$ ; therefore, twice the triangle  $ABC$  is equal to  $2A.T + 2B.T + 2C.T - 4T$ ; and consequently, once  $ABC = (A + B + C - 2)T$ ; hence every spherical triangle is measured by the sum of all its angles *minus* two right angles, multiplied by the tri-rectangular triangle.

*Cor. 1.* However many right angles there may be in the sum of the three angles minus two right angles, just so many tri-rectangular triangles, or eighths of the sphere, will the proposed triangle contain. If the angles, for example, are each equal to  $\frac{4}{3}$  of a right angle, the three angles will amount to 4 right angles, and the sum of the angles minus two right angles will be represented by  $4 - 2$  or 2; therefore the surface of the triangle will be equal to two tri-rectangular triangles, or to the fourth part of the whole surface of the sphere.

*Scholium.* While the spherical triangle  $ABC$  is compared with the tri-rectangular triangle, the spherical pyramid, which has  $ABC$  for its base, is compared with the tri-rectangular pyramid, and a similar proportion is found to subsist between them. The solid angle at the vertex of the pyramid, is in like manner compared with the solid angle at the vertex of the tri-rectangular pyramid. These comparisons are founded on the coincidence of the corresponding parts. If the bases of the

pyramids coincide, the pyramids themselves will evidently coincide, and likewise the solid angles at their vertices. From this, some consequences are deduced.

*First.* Two triangular spherical pyramids are to each other as their bases : and since a polygonal pyramid may always be divided into a certain number of triangular ones, it follows that any two spherical pyramids are to each other, as the polygons which form their bases.

*Second.* The solid angles at the vertices of these pyramids, are also as their bases ; hence, for comparing any two solid angles, we have merely to place their vertices at the centres of two equal spheres, and the solid angles will be to each other as the spherical polygons intercepted between their planes or faces.

The vertical angle of the tri-rectangular pyramid is formed by three planes at right angles to each other : this angle, which may be called a *right solid angle*, will serve as a very natural unit of measure for all other solid angles. If, for example, the area of the triangle is  $\frac{3}{4}$  of the tri-rectangular triangle, then the corresponding solid angle will also be  $\frac{3}{4}$  of the right solid angle.

#### PROPOSITION XXI. THEOREM.

*The surface of a spherical polygon is measured by the sum of all its angles, minus two right angles multiplied by the number of sides in the polygon less two, into the tri-rectangular triangle.*

From one of the vertices A, let diagonals AC, AD be drawn to all the other vertices ; the polygon ABCDE will be divided into as many triangles *minus* two as it has sides. But the surface of each triangle is measured by the sum of all its angles *minus* two right angles, into the tri-rectangular triangle ; and the sum of the angles in all the triangles is evidently the same as that of all the angles of the polygon ; hence, the surface of the polygon is equal to the sum of all its angles, diminished by twice as many right angles as it has sides less two, into the tri-rectangular triangle.

*Scholium.* Let  $s$  be the sum of all the angles in a spherical polygon,  $n$  the number of its sides, and  $T$  the tri-rectangular triangle ; the right angle being taken for unity, the surface of the polygon will be measured by

$$(s - 2(n - 2)) T, \text{ or } (s - 2n + 4) T$$

## APPENDIX.

### THE REGULAR POLYEDRONS.

A *regular polyedron* is one whose faces are all equal regular polygons, and whose solid angles are all equal to each other. There are five such polyedrons.

*First.* If the faces are equilateral triangles, polyedrons may be formed of them, having solid angles contained by three of those triangles, by four, or by five: hence arise three regular bodies, the *tetraedron*, the *octaedron*, the *icosaedron*. No other can be formed with equilateral triangles; for six angles of such a triangle are equal to four right angles, and cannot form a solid angle (Book VI. Prop. XX.).

*Secondly.* If the faces are squares, their angles may be arranged by threes: hence results the *hexaedron* or *cube*. Four angles of a square are equal to four right angles, and cannot form a solid angle.

*Thirdly.* In fine, if the faces are regular pentagons, their angles likewise may be arranged by threes: the regular *dodecaedron* will result.

We can proceed no farther: three angles of a regular hexagon are equal to four right angles; three of a heptagon are greater.

Hence there can only be five regular polyedrons; three formed with equilateral triangles, one with squares, and one with pentagons.

#### *Construction of the Tetraedron.*

Let  $ABC$  be the equilateral triangle which is to form one face of the tetraedron. At the point  $O$ , the centre of this triangle, erect  $OS$  perpendicular to the plane  $ABC$ ; terminate this perpendicular in  $S$ , so that  $AS=AB$ ; draw  $SB$ ,  $SC$ : the pyramid  $S-ABC$  will be the tetraedron required.

For, by reason of the equal distances  $OA$ ,  $OB$ ,  $OC$ , the oblique lines  $SA$ ,  $SB$ ,  $SC$ , are equally re-

moved from the perpendicular  $SO$ , and consequently equal (Book VI. Prop. V.). One of them  $SA=AB$ ; hence the four faces of the pyramid  $S-ABC$ , are triangles, equal to the given triangle  $ABC$ . And the solid angles of this pyramid are all equal, because each of them is formed by three equal plane angles: hence this pyramid is a regular tetraedron.

### *Construction of the Hexaedron.*

Let  $ABCD$  be a given square. On the base  $ABCD$ , construct a right prism whose altitude  $AE$  shall be equal to the side  $AB$ . The faces of this prism will evidently be equal squares; and its solid angles all equal, each being formed with three right angles: hence this prism is a regular hexaedron or cube.

The following propositions can be easily proved.

1. Any regular polyedron may be divided into as many regular pyramids as the polyedron has faces; the common vertex of these pyramids will be the centre of the polyedron; and at the same time, that of the inscribed and of the circumscribed sphere.

2. The solidity of a regular polyedron is equal to its surface multiplied by a third part of the radius of the inscribed sphere.

3. Two regular polyedrons of the same name, are two similar solids, and their homologous dimensions are proportional; hence the radii of the inscribed or the circumscribed spheres are to each other as the sides of the polyedrons.

4. If a regular polyedron is inscribed in a sphere, the planes drawn from the centre, through the different edges, will divide the surface of the sphere into as many spherical polygons, all equal and similar, as the polyedron has faces.

# APPLICATION OF ALGEBRA.

TO THE SOLUTION OF

## GEOMETRICAL PROBLEMS.

A problem is a question which requires a solution. A geometrical problem is one, in which certain parts of a geometrical figure are given or known, from which it is required to determine certain other parts.

When it is proposed to solve a geometrical problem by means of Algebra, the given parts are represented by the first letters of the alphabet, and the required parts by the final letters, and the relations which subsist between the known and unknown parts furnish the equations of the problem. The solution of these equations, when so formed, gives the solution of the problem.

No general rule can be given for forming the equations. The equations must be independent of each other, and their number equal to that of the unknown quantities introduced (Alg. Art. 103.). Experience, and a careful examination of all the conditions, whether explicit or implicit (Alg. Art. 94,) will serve as guides in stating the questions; to which may be added the following particular directions.

1st. Draw a figure which shall represent all the given parts, and all the required parts. Then draw such other lines as will establish the most simple relations between them. If an angle is given, it is generally best to let fall a perpendicular that shall lie opposite to it; and this perpendicular, if possible, should be drawn from the extremity of a given side.

2d. When two lines or quantities are connected in the same way with other parts of the figure or problem, it is in general, not best to use either of them separately; but to use their sum, their difference, their product, their quotient, or perhaps another line of the figure with which they are alike connected.

3d. When the area, or perimeter of a figure, is given, it is sometimes best to assume another figure similar to the proposed, having one of its sides equal to unity, or some other known quantity. A comparison of the two figures will often give a required part. We will add the following problems.\*

\* The following problems are selected from Hutton's Application of Algebra to Geometry, and the examples in Mensuration from his treatise on that subject

## PROBLEM I.

*In a right angled triangle BAC, having given the base BA, and the sum of the hypotenuse and perpendicular, it is required to find the hypotenuse and perpendicular.*

Put  $BA=c=3$ ,  $BC=x$ ,  $AC=y$  and the sum of the hypotenuse and perpendicular equal to  $s=9$

Then,  $x+y=s=9$ .

and  $x^2=y^2+c^2$  (Bk. IV. Prop. XI.)

From 1st equ:  $x=s-y$

and  $x^2=s^2-2sy+y^2$

By subtracting,  $0=s^2-2sy-c^2$

or  $2sy=s^2-c^2$

hence,  $y=\frac{s^2-c^2}{2s}=4=AC$

Therefore  $x+4=9$  or  $x=5=BC$ .

## PROBLEM II.

*In a right angled triangle, having given the hypotenuse, and the sum of the base and perpendicular, to find these two sides.*

Put  $BC=a=5$ ,  $BA=x$ ,  $AC=y$  and the sum of the base and perpendicular  $=s=7$

Then  $x+y=s=7$

and  $x^2+y^2=a^2$

From first equation  $x=s-y$

or  $x^2=s^2-2sy+y^2$

Hence,  $y^2=a^2-s^2+2sy-y^2$

or  $2y^2-2sy=a^2-s^2$

or  $y^2-sy=\frac{a^2-s^2}{2}$

By completing the square  $y^2-sy+\frac{1}{4}s^2=\frac{1}{2}a^2-\frac{1}{4}s^2$

or  $y=\frac{1}{2}s\pm\sqrt{\frac{1}{2}a^2-\frac{1}{4}s^2}=4$  or 3

Hence  $x=\frac{1}{2}s\mp\sqrt{\frac{1}{2}a^2-\frac{1}{4}s^2}=3$  or 4

PROBLEM III.

*In a rectangle, having given the diagonal and perimeter, to find the sides.*

Let ABCD be the proposed rectangle.  
Put  $AC=d=10$ , the perimeter  $=2a=28$ , or  
 $AB+BC=a=14$ : also put  $AB=x$  and  $BC=y$ .

Then,  $x^2+y^2=d^2$

and  $x+y=a$

From which equations we obtain,

$$y = \frac{1}{2}a \pm \sqrt{\frac{1}{2}d^2 - \frac{1}{4}a^2} = 8 \text{ or } 6,$$

and  $x = \frac{1}{2}a \mp \sqrt{\frac{1}{2}d^2 - \frac{1}{4}a^2} = 6 \text{ or } 8.$

PROBLEM IV.

*Having given the base and perpendicular of a triangle, to find the side of an inscribed square.*

Let ABC be the triangle and HEFG the inscribed square. Put  $AB=b$ ,  $CD=a$ ,  
and  $HE$  or  $GH=x$ : then  $CI=a-x$ .

We have by similar triangles

$$AB : CD :: GF : CI$$

or  $b : a :: x : a-x$

Hence,  $ab-bx=ax$

or  $x = \frac{ab}{a+b}$  = the side of the inscribed square ;

which, therefore, depends only on the base and altitude of the triangle.

PROBLEM V.

*In an equilateral triangle, having given the lengths of the three perpendiculars drawn from a point within, on the three sides: to determine the sides of the triangle.*

Let  $ABC$  be the equilateral triangle;  $DG$ ,  $DE$  and  $DF$  the given perpendiculars let fall from  $D$  on the sides. Draw  $DA$ ,  $DB$ ,  $DC$  to the vertices of the angles, and let fall the perpendicular  $CH$  on the base. Let  $DG=a$ ,  $DE=b$ , and  $DF=c$ : put one of the equal sides  $AB$

$=2x$ ; hence  $AH=x$ , and  $CH=\sqrt{AC^2-AH^2}=\sqrt{4x^2-x^2}=\sqrt{3x^2}=x\sqrt{3}$ .

Now since the area of a triangle is equal to half its base into the altitude, (Bk. IV. Prop. VI.)

$$\frac{1}{2}AB \times CH = x \times x\sqrt{3} = x^2\sqrt{3} = \text{triangle } ACB$$

$$\frac{1}{2}AB \times DG = x \times a = ax = \text{triangle } ADB$$

$$\frac{1}{2}BC \times DE = x \times b = bx = \text{triangle } BCD$$

$$\frac{1}{2}AC \times DF = x \times c = cx = \text{triangle } ACD$$

But the three last triangles make up, and are consequently equal to, the first; hence,

$$x^2\sqrt{3} = ax + bx + cx = x(a+b+c);$$

or

$$x\sqrt{3} = a+b+c$$

therefore,

$$x = \frac{a+b+c}{\sqrt{3}}$$

**REMARK.** Since the perpendicular  $CH$  is equal to  $x\sqrt{3}$ , it is consequently equal to  $a+b+c$ : that is, the perpendicular let fall from either angle of an equilateral triangle on the opposite side, is equal to the sum of the three perpendiculars let fall from any point within the triangle on the sides respectively.

#### PROBLEM VI.

In a right angled triangle, having given the base and the difference between the hypotenuse and perpendicular, to find the sides.

#### PROBLEM VII.

In a right angled triangle, having given the hypotenuse and the difference between the base and perpendicular, to determine the triangle.

## PROBLEM VIII.

Having given the area of a rectangle inscribed in a given triangle ; to determine the sides of the rectangle.

## PROBLEM IX.

In a triangle, having given the ratio of the two sides, together with both the segments of the base made by a perpendicular from the vertical angle ; to determine the triangle.

## PROBLEM X.

In a triangle, having given the base, the sum of the other two sides, and the length of a line drawn from the vertical angle to the middle of the base ; to find the sides of the triangle.

## PROBLEM XI.

In a triangle, having given the two sides about the vertical angle, together with the line bisecting that angle and terminating in the base ; to find the base.

## PROBLEM XII.

To determine a right angled triangle, having given the lengths of two lines drawn from the acute angles to the middle of the opposite sides.

## PROBLEM XIII.

To determine a right-angled triangle, having given the perimeter and the radius of the inscribed circle.

## PROBLEM XIV.

To determine a triangle, having given the base, the perpendicular and the ratio of the two sides.

## PROBLEM XV.

To determine a right angled triangle, having given the hypotenuse, and the side of the inscribed square.

## PROBLEM XVI.

To determine the radii of three equal circles, described within and tangent to, a given circle, and also tangent to each other.

## PROBLEM XVII

In a right angled triangle, having given the perimeter and the perpendicular let fall from the right angle on the hypotenuse, to determine the triangle.

## PROBLEM XVIII.

To determine a right angled triangle, having given the hypotenuse and the difference of two lines drawn from the two acute angles to the centre of the inscribed circle.

## PROBLEM XIX.

To determine a triangle, having given the base, the perpendicular, and the difference of the two other sides.

## PROBLEM XX.

To determine a triangle, having given the base, the perpendicular and the rectangle of the two sides.

## PROBLEM XXI.

To determine a triangle, having given the lengths of three lines drawn from the three angles to the middle of the opposite sides.

## PROBLEM XXII.

In a triangle, having given the three sides, to find the radius of the inscribed circle.

## PROBLEM XXIII.

To determine a right angled triangle, having given the side of the inscribed square, and the radius of the inscribed circle.

## PROBLEM XXIV.

To determine a right angled triangle, having given the hypotenuse and radius of the inscribed circle.

## PROBLEM XXV.

To determine a triangle, having given the base, the line bisecting the vertical angle, and the diameter of the circumscribing circle.

## PLANE TRIGONOMETRY.

In every triangle there are six parts: three sides and three angles. These parts are so related to each other, that if a certain number of them be known or given, the remaining ones can be determined.

*Plane Trigonometry* explains the methods of finding, by calculation, the unknown parts of a rectilineal triangle, when a sufficient number of the six parts are given.

When three of the six parts are known, and one of them is a side, the remaining parts can always be found. If the three angles were given, it is obvious that the problem would be indeterminate, since all similar triangles would satisfy the conditions.

It has already been shown, in the problems annexed to Book III., how rectilineal triangles are constructed by means of three given parts. But these constructions, which are called *graphic methods*, though perfectly correct in theory, would give only a moderate approximation in practice, on account of the imperfection of the instruments required in constructing them. Trigonometrical methods, on the contrary, being independent of all mechanical operations, give solutions with the utmost accuracy.

These methods are founded upon the properties of lines called trigonometrical lines, which furnish a very simple mode of expressing the relations between the sides and angles of triangles.

We shall first explain the properties of those lines, and the principal formulas derived from them; formulas which are of great use in all the branches of mathematics, and which even furnish means of improvement to algebraical analysis. We shall next apply those results to the solution of rectilineal triangles.

## DIVISION OF THE CIRCUMFERENCE.

I. For the purposes of trigonometrical calculation, the circumference of the circle is divided into 360 equal parts, called degrees; each degree into 60 equal parts, called minutes; and each minute into 60 equal parts, called seconds.

The semicircumference, or the measure of two right angles, contains 180 degrees; the quarter of the circumference, usually denominated the quadrant, and which measures the right angle, contains 90 degrees.

II. Degrees, minutes, and seconds, are respectively desig-

The *secant* of an arc is the line drawn from the centre of the circle through one extremity of the arc and limited by the tangent drawn through the other extremity. Thus CT is the secant of the arc AM, or of the angle ACM.

The *versed sine* of an arc, is the part of the diameter intercepted between one extremity of the arc and the foot of the sine. Thus, AP is the versed sine of the arc AM, or the angle ACM.

These four lines MP, AT, CT, AP, are dependent upon the arc AM, and are always determined by it and the radius; they are thus designated :

$$\begin{aligned} MP &= \sin AM, \text{ or } \sin ACM, \\ AT &= \tan AM, \text{ or } \tan ACM, \\ CT &= \sec AM, \text{ or } \sec ACM, \\ AP &= \text{ver-sin } AM, \text{ or } \text{ver-sin } ACM. \end{aligned}$$

VI. Having taken the arc AD equal to a quadrant, from the points M and D draw the lines MQ, DS, perpendicular to the radius CD, the one terminated by that radius, the other terminated by the radius CM produced; the lines MQ, DS, and CS, will, in like manner, be the sine, tangent, and secant of the arc MD, the complement of AM. For the sake of brevity, they are called the *cosine*, *cotangent*, and *cosecant*, of the arc AM, and are thus designated :

$$\begin{aligned} MQ &= \cos AM, \text{ or } \cos ACM, \\ DS &= \cot AM, \text{ or } \cot ACM, \\ CS &= \text{cosec } AM, \text{ or } \text{cosec } ACM. \end{aligned}$$

In general, A being any arc or angle, we have

$$\begin{aligned} \cos A &= \sin (90^\circ - A), \\ \cot A &= \tan (90^\circ - A), \\ \text{cosec } A &= \sec (90^\circ - A). \end{aligned}$$

The triangle MQC is, by construction, equal to the triangle CPM; consequently CP=MQ: hence in the right-angled triangle CMP, whose hypotenuse is equal to the radius, the two sides MP, CP are the sine and cosine of the arc AM: hence, the cosine of an arc is equal to that part of the radius intercepted between the centre and foot of the sine.

The triangles CAT, CDS, are similar to the equal triangles CPM, CQM; hence they are similar to each other. From these principles, we shall very soon deduce the different relations which exist between the lines now defined: before doing so, however, we must examine the changes which those lines undergo, when the arc to which they relate increases from zero to  $180^\circ$ .

The angle ACD is called the *first quadrant*; the angle DCB, the *second quadrant*; the angle BCE, the *third quadrant*; and the angle ECA, the *fourth quadrant*.

As to the tangent, it increases very rapidly as the point  $M$  approaches  $D$ ; and finally when this point reaches  $D$ , the tangent properly exists no longer, because the lines  $AT$ ,  $CD$ , being parallel, cannot meet. This is expressed by saying that the tangent of  $90^\circ$  is infinite; and we write  $\text{tang } 90^\circ = \infty$

The complement of  $90^\circ$  being zero, we have

$$\text{tang } 0 = \cot 90^\circ \text{ and } \cot 0 = \text{tang } 90^\circ.$$

Hence  $\cot 90^\circ = 0$ , and  $\cot 0 = \infty$ .

X. The point  $M$  continuing to advance from  $D$  towards  $B$ , the sines diminish and the cosines increase. Thus  $M'P'$  is the sine of the arc  $AM'$ , and  $M'Q$ , or  $CP'$  its cosine. But the arc  $M'B$  is the supplement of  $AM'$ , since  $AM' + M'B$  is equal to a semicircumference; besides, if  $M'M$  is drawn parallel to  $AB$ , the arcs  $AM$ ,  $BM'$ , which are included between parallels, will evidently be equal, and likewise the perpendiculars or sines  $MP$ ,  $M'P'$ . Hence, *the sine of an arc or of an angle is equal to the sine of the supplement of that arc or angle.*

The arc or angle  $A$  has for its supplement  $180^\circ - A$ : hence generally, we have

$$\sin A = \sin (180^\circ - A.)$$

The same property might also be expressed by the equation

$$\sin (90^\circ + B) = \sin (90^\circ - B),$$

$B$  being the arc  $DM$  or its equal  $DM'$ .

XI. The same arcs  $AM$ ,  $AM'$ , which are supplements of each other, and which have equal sines, have also equal cosines  $CP$ ,  $CP'$ ; but it must be observed, that these cosines lie in different directions. The line  $CP$  which is the cosine of the arc  $AM$ , has the origin of its value at the centre  $C$ , and is estimated in the direction from  $C$  towards  $A$ ; while  $CP'$ , the cosine of  $AM'$  has also the origin of its value at  $C$ , but is estimated in a contrary direction, from  $C$  towards  $B$ .

Some notation must obviously be adopted to distinguish the one of such equal lines from the other; and that they may both be expressed analytically, *and in the same general formula*, it is necessary to consider all lines which are estimated in one direction as *positive*, and those which are estimated in the contrary direction as *negative*. If, therefore, the cosines which are estimated from  $C$  towards  $A$  be considered as positive, those estimated from  $C$  towards  $B$ , must be regarded as negative. Hence, generally, we shall have,

$$\cos A = -\cos (180^\circ - A)$$

that is, *the cosine of an arc or angle is equal to the cosine of its supplement taken negatively.*

The necessity of changing the algebraic sign to correspond

with the change of direction in the trigonometrical line, may be illustrated by the following example. The versed sine  $AP$  is equal to the radius  $CA$  minus  $CP$  the cosine  $AM$ : that is,

$$\text{ver-sin } AM = R - \cos AM.$$

Now when the arc  $AM$  becomes  $AM'$  the versed sine  $AP$ , becomes  $AP'$ , that is equal to  $R + CP'$ . But this expression cannot be derived from the formula,

$$\text{ver-sin } AM = R - \cos AM,$$

unless we suppose the cosine  $AM$  to become negative as soon as the arc  $AM$  becomes greater than a quadrant.

At the point  $B$  the cosine becomes equal to  $-R$ ; that is,

$$\cos 180^\circ = -R.$$

For all arcs, such as  $ADBN'$ , which terminate in the third quadrant, the cosine is estimated from  $C$  towards  $B$ , and is consequently negative. At  $E$  the cosine becomes zero, and for all arcs which terminate in the fourth quadrant the cosines are estimated from  $C$  towards  $A$ , and are consequently positive.

The sines of all the arcs which terminate in the first and second quadrants, are estimated above the diameter  $BA$ , while the sines of those arcs which terminate in the third and fourth quadrants are estimated below it. Hence, considering the former as positive, we must regard the latter as negative.

XII. Let us now see what sign is to be given to the tangent of an arc. The tangent of the arc  $AM$  falls above the line  $BA$ , and we have already regarded the lines estimated in the direction  $AT$  as positive: therefore the tangents of all arcs which terminate in the first quadrant will be positive. But the tangent of the arc  $AM'$ , greater than  $90^\circ$ , is determined by the intersection of the two lines  $M'C$  and  $AT$ . These lines, however, do not meet in the direction  $AT$ ; but they meet in the opposite direction  $AV$ . But since the tangents estimated in the direction  $AT$  are positive, those estimated in the direction  $AV$  must be negative: therefore, *the tangents of all arcs which terminate in the second quadrant will be negative.*

When the point  $M'$  reaches the point  $B$  the tangent  $AV$  will become equal to zero: that is,

$$\text{tang } 180^\circ = 0.$$

When the point  $M'$  passes the point  $B$ , and comes into the position  $N'$ , the tangent of the arc  $ADN'$  will be the line  $AT$ :

hence, *the tangents of all arcs which terminate in the third quadrant are positive.*

At E the tangent becomes infinite : that is.

$$\text{tang } 270^\circ = \infty.$$

When the point has passed along into the fourth quadrant to N, the tangent of the arc ADN'N will be the line AV : hence, *the tangents of all arcs which terminate in the fourth quadrant are negative.*

The cotangents are estimated from the line ED. Those which lie on the side DS are regarded as positive, and those which lie on the side DS' as negative. Hence, *the cotangents are positive in the first quadrant, negative in the second, positive in the third, and negative in the fourth.* When the point M is at B the cotangent is infinite ; when at E it is zero : hence,

$$\cot 180^\circ = -\infty ; \cot 270^\circ = 0.$$

Let  $q$  stand for a quadrant ; then the following table will show the signs of the trigonometrical lines in the different quadrants.

|           | $1q$ | $2q$ | $3q$ | $4q$ |
|-----------|------|------|------|------|
| Sine      | +    | +    | —    | —    |
| Cosine    | +    | —    | —    | +    |
| Tangent   | +    | —    | +    | —    |
| Cotangent | +    | —    | +    | —    |

XIII. In trigonometry, the sines, cosines, &c. of arcs or angles greater than  $180^\circ$  do not require to be considered ; the angles of triangles, rectilineal as well as spherical, and the sides of the latter, being always comprehended between 0 and  $180^\circ$ . But in various applications of trigonometry, there is frequently occasion to reason about arcs greater than the semicircumference, and even about arcs containing several circumferences. It will therefore be necessary to find the expression of the sines and cosines of those arcs whatever be their magnitude.

We generally consider the arcs as positive which are estimated from A in the direction ADB, and then those arcs must be regarded as negative which are estimated in the contrary direction AEB.

We observe, in the first place, that two equal arcs AM, AN with contrary algebraic signs, have equal sines MP, PN, with contrary algebraic signs ; while the cosine CP is the same for both.

The equal tangents AT, AV, as well as the equal cotangents DS, DS', have also contrary algebraic signs. Hence, calling  $x$  the arc, we have in general,

$$\begin{aligned} \sin (-x) &= -\sin x \\ \cos (-x) &= \cos x \\ \text{tang } (-x) &= -\text{tang } x \\ \cot (-x) &= -\cot x \end{aligned}$$

By considering the arc  $AM$ , and its supplement  $AM'$ , and recollecting what has been said, we readily see that,

$$\sin (\text{an arc}) = \sin (\text{its supplement})$$

$$\cos (\text{an arc}) = -\cos (\text{its supplement})$$

$$\text{tang} (\text{an arc}) = -\text{tang} (\text{its supplement})$$

$$\cot (\text{an arc}) = -\cot (\text{its supplement}).$$

It is no less evident, that if one or several circumferences were added to any arc  $AM$ , it would still terminate exactly at the point  $M$ , and the arc thus increased would have the same sine as the arc  $AM$ ; hence if  $C$  represent a whole circumference or  $360^\circ$ , we shall have  $\sin x = \sin (C + x) = \sin x = \sin (2C + x)$ , &c.

The same observation is applicable to the cosine, tangent, &c.

Hence it appears, that whatever be the magnitude of  $x$  the proposed arc, its sine may always be expressed, with a proper sign, by the sine of an arc less than  $180^\circ$ . For, in the first place, we may subtract  $360^\circ$  from the arc  $x$  as often as they are contained in it; and  $y$  being the remainder, we shall have  $\sin x = \sin y$ . Then if  $y$  is greater than  $180^\circ$ , make  $y = 180^\circ + z$ , and we have  $\sin y = -\sin z$ . Thus all the cases are reduced to that in which the proposed arc is less than  $180^\circ$ ; and since we farther have  $\sin (90^\circ + x) = \sin (90^\circ - x)$ , they are likewise ultimately reducible to the case, in which the proposed arc is between zero and  $90^\circ$ .

**XIV.** The cosines are always reducible to sines, by means of the formula  $\cos A = \sin (90^\circ - A)$ ; or if we require it, by means of the formula  $\cos A = \sin (90^\circ + A)$ : and thus, if we can find the value of the sines in all possible cases, we can also find that of the cosines. Besides, as has already been shown, that the negative cosines are separated from the positive cosines by the diameter  $DE$ ; all the arcs whose extremities fall on the right side of  $DE$ , having a positive cosine, while those whose extremities fall on the left have a negative cosine.

Thus from  $0^\circ$  to  $90^\circ$  the cosines are positive; from  $90^\circ$  to  $270^\circ$  they are negative; from  $270^\circ$  to  $360^\circ$  they again become positive; and after a whole revolution they assume the same values as in the preceding revolution, for  $\cos (360^\circ + x) = \cos x$ .

From these explanations, it will evidently appear, that the sines and cosines of the various arcs which are multiples of the quadrant have the following values :

|                      |                       |                       |                      |
|----------------------|-----------------------|-----------------------|----------------------|
| $\sin 0^\circ = 0$   | $\sin 90^\circ = R$   | $\cos 0^\circ = R$    | $\cos 90^\circ = 0$  |
| $\sin 180^\circ = 0$ | $\sin 270^\circ = -R$ | $\cos 180^\circ = -R$ | $\cos 270^\circ = 0$ |
| $\sin 360^\circ = 0$ | $\sin 450^\circ = R$  | $\cos 360^\circ = R$  | $\cos 450^\circ = 0$ |
| $\sin 540^\circ = 0$ | $\sin 630^\circ = -R$ | $\cos 540^\circ = -R$ | $\cos 630^\circ = 0$ |
| $\sin 720^\circ = 0$ | $\sin 810^\circ = R$  | $\cos 720^\circ = R$  | $\cos 810^\circ = 0$ |
| &c.                  | &c.                   | &c.                   | &c.                  |

And generally,  $k$  designating any whole number we shall have

$$\begin{aligned} \sin 2k \cdot 90^\circ &= 0, & \cos (2k+1) \cdot 90^\circ &= 0, \\ \sin (4k+1) \cdot 90^\circ &= R, & \cos 4k \cdot 90^\circ &= R, \\ \sin (4k-1) \cdot 90^\circ &= -R, & \cos (4k+2) \cdot 90^\circ &= -R. \end{aligned}$$

What we have just said concerning the sines and cosines renders it unnecessary for us to enter into any particular detail respecting the tangents, cotangents, &c. of arcs greater than  $180^\circ$ ; the value of these quantities are always easily deduced from those of the sines and cosines of the same arcs : as we shall see by the formulas, which we now proceed to explain.

#### THEOREMS AND FORMULAS RELATING TO SINES, COSINES, TANGENTS, &c.

**XV.** *The sine of an arc is half the chord which subtends a double arc.*

For the radius  $CA$ , perpendicular to the chord  $MN$ , bisects this chord, and likewise the arc  $MAN$ ; hence  $MP$ , the sine of the arc  $MA$ , is half the chord  $MN$  which subtends the arc  $MAN$ , the double of  $MA$ .

The chord which subtends the sixth part of the circumference is equal to the radius ; hence

$$\sin \frac{360^\circ}{12} \text{ or } \sin 30^\circ = \frac{1}{2}R,$$

in other words, the sine of a third part of the right angle is equal to the half of the radius.

By means of these formulas, several results, which have already been obtained concerning the trigonometrical lines may be confirmed. If, for example, we make  $A=90^\circ$ , we shall have  $\sin A=R$ ,  $\cos A=0$ ; and consequently  $\tan 90^\circ = \frac{R^2}{0}$ , an expression which designates an infinite quantity; for the quotient of radius divided by a very small quantity, is very great, and increases as the divisor diminishes; hence, the quotient of the radius divided by zero is greater than any finite quantity.

The tangent being equal to  $R \cdot \frac{\sin}{\cos}$ ; and cotangent to  $R \cdot \frac{\cos}{\sin}$ ; it follows that tangent and cotangent will both be positive when the sine and cosine have like algebraic signs, and both negative, when the sine and cosine have contrary algebraic signs. Hence, the tangent and cotangent have the same sign in the diagonal quadrants: that is, positive in the 1st and 3d, and negative in the 2d and 4th; results agreeing with those of Art. XII.

The Algebraic signs of the secants and cosecants are readily determined. For, the secant is equal to radius square divided by the cosine, and since radius square is always positive, it follows that the algebraic sign of the secant will depend on that of the cosine: hence, it is positive in the 1st and 4th quadrants and negative in the 2nd and 3rd.

Since the cosecant is equal to radius square divided by the sine, it follows that its sign will depend on the algebraic sign of the sine: hence, it will be positive in the 1st and 2nd quadrants and negative in the 3rd and 4th.

XVIII. The formulas of the preceding Article, combined with each other and with the equation  $\sin^2 A + \cos^2 A = R^2$ , furnish some others worthy of attention.

First we have  $R^2 + \tan^2 A = R^2 + \frac{R^2 \sin^2 A}{\cos^2 A} = \frac{R^2 (\sin^2 A + \cos^2 A)}{\cos^2 A} = \frac{R^4}{\cos^2 A}$ ; hence  $R^2 + \tan^2 A = \sec^2 A$ , a

formula which might be immediately deduced from the right-angled triangle CAT. By these formulas, or by the right-angled triangle CDS, we have also  $R^2 + \cot^2 A = \operatorname{cosec}^2 A$ .

Lastly, by taking the product of the two formulas  $\tan A = \frac{R \sin A}{\cos A}$ , and  $\cot A = \frac{R \cos A}{\sin A}$ , we have  $\tan A \times \cot A = R^2$ , a

formula which gives  $\cot A = \frac{R^2}{\tan A}$ , and  $\tan A = \frac{R^2}{\cot A}$ .

We likewise have  $\cot B = \frac{R^2}{\tan B}$ .

Hence  $\cot A : \cot B :: \tan B : \tan A$ ; that is, *the cotangents of two arcs are reciprocally proportional to their tangents.*

The formula  $\cot A \times \tan A = R^2$  might be deduced immediately, by comparing the similar triangles CAT, CDS, which give  $AT : CA :: CD : DS$ , or  $\tan A : R :: R : \cot A$

XIX. *The sines and cosines of two arcs, a and b, being given, it is required to find the sine and cosine of the sum or difference of these arcs.*

Let the radius  $AC = R$ , the arc  $AB = a$ , the arc  $BD = b$ , and consequently  $ABD = a + b$ . From the points B and D, let fall the perpendiculars BE, DF upon AC; from the point D, draw DI perpendicular to BC; lastly, from the point I draw IK perpendicular, and IL parallel to, AC.

The similar triangles BCE, ICK, give the proportions,

$$CB : CI :: BE : IK, \text{ or } R : \cos b :: \sin a : IK = \frac{\sin a \cos b}{R}$$

$$CB : CI :: CE : CK, \text{ or } R : \cos b :: \cos a : CK = \frac{\cos a \cos b}{R}$$

The triangles DIL, CBE, having their sides perpendicular, each to each, are similar, and give the proportions,

$$CB : DI :: CE : DL, \text{ or } R : \sin b :: \cos a : DL = \frac{\cos a \sin b}{R}$$

$$CB : DI :: BE : IL, \text{ or } R : \sin b :: \sin a : IL = \frac{\sin a \sin b}{R}$$

But we have

$IK + DL = DF = \sin(a + b)$ , and  $CK - IL = CF = \cos(a + b)$ .  
Hence

$$\sin(a + b) = \frac{\sin a \cos b + \sin b \cos a}{R}$$

$$\cos(a + b) = \frac{\cos a \cos b - \sin a \sin b}{R}$$

The values of  $\sin(a - b)$  and of  $\cos(a - b)$  might be easily deduced from these two formulas; but they may be found directly by the same figure. For, produce the sine DI till it meets the circumference at M; then we have  $BM = BD = b$ , and  $MI = ID = \sin b$ . Through the point M, draw MP perpendicular, and MN parallel to, AC: since  $MI = DI$ , we have  $MN = IL$ , and  $IN = DL$ . But we have  $IK - IN = MP = \sin(a - b)$ , and  $CK + MN = CP = \cos(a - b)$ ; hence

$$\sin (a-b) = \frac{\sin a \cos b - \sin b \cos a}{R}$$

$$\cos (a-b) = \frac{\cos a \cos b + \sin a \sin b}{R}$$

These are the formulas which it was required to find.

The preceding demonstration may seem defective in point of generality, since, in the figure which we have followed, the arcs  $a$  and  $b$ , and even  $a+b$ , are supposed to be less than  $90^\circ$ . But first the demonstration is easily extended to the case in which  $a$  and  $b$  being less than  $90^\circ$ , their sum  $a+b$  is greater than  $90^\circ$ . Then the point  $F$  would fall on the prolongation of  $AC$ , and the only change required in the demonstration would be that of taking  $\cos (a+b) = -CF'$ ; but as we should, at the same time, have  $CF' = I'L' - CK'$ , it would still follow that  $\cos (a+b) = CK' - I'L'$ , or  $R \cos (a+b) = \cos a \cos b - \sin a \sin b$ . And whatever be the values of the arcs  $a$  and  $b$ , it is easily shown that the formulas are true: hence we may regard them as established for all arcs. We will repeat and number the formulas for the purpose of more convenient reference.

$$\sin (a+b) = \frac{\sin a \cos b + \sin b \cos a}{R} \quad (1.).$$

$$\sin (a-b) = \frac{\sin a \cos b - \sin b \cos a}{R} \quad (2.).$$

$$\cos (a+b) = \frac{\cos a \cos b - \sin a \sin b}{R} \quad (3.)$$

$$\cos (a-b) = \frac{\cos a \cos b + \sin a \sin b}{R} \quad (4.)$$

XX. If, in the formulas of the preceding Article, we make  $b=a$ , the first and the third will give

$$\sin 2a = \frac{2 \sin a \cos a}{R}, \quad \cos 2a = \frac{\cos^2 a - \sin^2 a}{R} = \frac{2 \cos^2 a - R^2}{R}$$

formulas which enable us to find the sine and cosine of the double arc, when we know the sine and cosine of the arc itself.

To express the  $\sin a$  and  $\cos a$  in terms of  $\frac{1}{2}a$ , put  $\frac{1}{2}a$  for  $a$ , and we have

$$\sin a = \frac{2 \sin \frac{1}{2}a \cos \frac{1}{2}a}{R}, \quad \cos a = \frac{\cos^2 \frac{1}{2}a - \sin^2 \frac{1}{2}a}{R}.$$

To find the sine and cosine of  $\frac{1}{2}a$  in terms of  $a$ , take the equations

$$\cos^2 \frac{1}{2}a + \sin^2 \frac{1}{2}a = R^2, \quad \text{and} \quad \cos^2 \frac{1}{2}a - \sin^2 \frac{1}{2}a = R \cos a,$$

there results by adding and subtracting

$$\cos^2 \frac{1}{2}a = \frac{1}{2}R^2 + \frac{1}{2}R \cos a, \quad \text{and} \quad \sin^2 \frac{1}{2}a = \frac{1}{2}R^2 - \frac{1}{2}R \cos a;$$

whence

$$\sin \frac{1}{2}a = \sqrt{\left(\frac{1}{2}R^2 - \frac{1}{2}R \cos a\right)} = \frac{1}{2}\sqrt{2R^2 - 2R \cos a}.$$

$$\cos \frac{1}{2}a = \sqrt{\left(\frac{1}{2}R^2 + \frac{1}{2}R \cos a\right)} = \frac{1}{2}\sqrt{2R^2 + 2R \cos a}.$$

If we put  $2a$  in the place of  $a$ , we shall have,

$$\sin a = \sqrt{\left(\frac{1}{2}R^2 - \frac{1}{2}R \cos 2a\right)} = \frac{1}{2}\sqrt{2R^2 - 2R \cos 2a}.$$

$$\cos a = \sqrt{\left(\frac{1}{2}R^2 + \frac{1}{2}R \cos 2a\right)} = \frac{1}{2}\sqrt{2R^2 + 2R \cos 2a}.$$

Making, in the two last formulas,  $a=45^\circ$ , gives  $\cos 2a=0$ , and

$$\sin 45^\circ = \sqrt{\frac{1}{2}R^2} = R\sqrt{\frac{1}{2}}; \text{ and also, } \cos 45^\circ = \sqrt{\frac{1}{2}R^2} = R\sqrt{\frac{1}{2}}.$$

Next, make  $a=22^\circ 30'$ , which gives  $\cos 2a=R\sqrt{\frac{1}{2}}$ , and we have

$$\sin 22^\circ 30' = R\sqrt{\frac{1}{2} - \frac{1}{2}\sqrt{\frac{1}{2}}} \text{ and } \cos 22^\circ 30' = R\sqrt{\frac{1}{2} + \frac{1}{2}\sqrt{\frac{1}{2}}}.$$

XXI. If we multiply together formulas (1.) and (2.) Art. XIX. and substitute for  $\cos^2 a$ ,  $R^2 - \sin^2 a$ , and for  $\cos^2 b$ ,  $R^2 - \sin^2 b$ ; we shall obtain, after reducing and dividing by  $R^2$ ,  $\sin(a+b)\sin(a-b) = \sin^2 a - \sin^2 b = (\sin a + \sin b)(\sin a - \sin b)$ .

or,  $\sin(a-b) : \sin a - \sin b :: \sin a + \sin b : \sin(a+b)$ .

XXII. The formulas of Art. XIX. furnish a great number of consequences; among which it will be enough to mention those of most frequent use. By adding and subtracting we obtain the four which follow,

$$\sin(a+b) + \sin(a-b) = \frac{2}{R} \sin a \cos b.$$

$$\sin(a+b) - \sin(a-b) = \frac{2}{R} \sin b \cos a.$$

$$\cos(a+b) + \cos(a-b) = \frac{2}{R} \cos a \cos b.$$

$$\cos(a-b) - \cos(a+b) = \frac{2}{R} \sin a \sin b.$$

and which serve to change a product of several sines or cosines into *linear* sines or cosines, that is, into sines and cosines multiplied only by constant quantities.

XXIII. If in these formulas we put  $a+b=p$ ,  $a-b=q$ , which gives  $a = \frac{p+q}{2}$ ,  $b = \frac{p-q}{2}$ , we shall find

$$\sin p + \sin q = \frac{2}{R} \sin \frac{1}{2}(p+q) \cos \frac{1}{2}(p-q) \quad (1.)$$

$$\sin p - \sin q = \frac{2}{R} \sin \frac{1}{2}(p-q) \cos \frac{1}{2}(p+q) \quad (2.)$$

$$\cos p + \cos q = \frac{2}{R} \cos \frac{1}{2}(p+q) \cos \frac{1}{2}(p-q) \quad (3.)$$

$$\cos q - \cos p = \frac{2}{R} \sin \frac{1}{2}(p+q) \sin \frac{1}{2}(p-q) \quad (4.)$$

If we make  $q=0$ , we shall obtain,

$$\sin p = \frac{2 \sin \frac{1}{2} p \cos \frac{1}{2} p}{R}$$

$$R + \cos p = \frac{2 \cos^2 \frac{1}{2} p}{R}$$

$$R - \cos p = \frac{2 \sin^2 \frac{1}{2} p}{R} : \text{hence}$$

$$\frac{\sin p}{R + \cos p} = \frac{\tan \frac{1}{2} p}{R} = \frac{R}{\cot \frac{1}{2} p}$$

$$\frac{\sin p}{R - \cos p} = \frac{\cot \frac{1}{2} p}{R} = \frac{R}{\tan \frac{1}{2} p} :$$

formulas which are often employed in trigonometrical calculations for reducing two terms to a single one.

XXIV. From the first four formulas of Art XXIII. and the first of Art. XX., dividing, and considering that  $\frac{\sin a}{\cos a} = \frac{\tan a}{R} = \frac{R}{\cot a}$  we derive the following :

$$\frac{\sin p + \sin q}{\sin p - \sin q} = \frac{\sin \frac{1}{2} (p+q) \cos \frac{1}{2} (p-q)}{\cos \frac{1}{2} (p+q) \sin \frac{1}{2} (p-q)} = \frac{\tan \frac{1}{2} (p+q)}{\tan \frac{1}{2} (p-q)}$$

$$\frac{\sin p + \sin q}{\cos p + \cos q} = \frac{\sin \frac{1}{2} (p+q)}{\cos \frac{1}{2} (p+q)} = \frac{\tan \frac{1}{2} (p+q)}{R}$$

$$\frac{\sin p + \sin q}{\cos q - \cos p} = \frac{\cos \frac{1}{2} (p-q)}{\sin \frac{1}{2} (p-q)} = \frac{\cot \frac{1}{2} (p-q)}{R}$$

$$\frac{\sin p - \sin q}{\cos p + \cos q} = \frac{\sin \frac{1}{2} (p-q)}{\cos \frac{1}{2} (p-q)} = \frac{\tan \frac{1}{2} (p-q)}{R}$$

$$\frac{\sin p - \sin q}{\cos q - \cos p} = \frac{\cos \frac{1}{2} (p+q)}{\sin \frac{1}{2} (p+q)} = \frac{\cot \frac{1}{2} (p+q)}{R}$$

$$\frac{\cos p + \cos q}{\cos q - \cos p} = \frac{\cos \frac{1}{2} (p+q) \cos \frac{1}{2} (p-q)}{\sin \frac{1}{2} (p+q) \sin \frac{1}{2} (p-q)} = \frac{\cot \frac{1}{2} (p+q)}{\tan \frac{1}{2} (p-q)}$$

$$\frac{\sin p + \sin q}{\sin (p+q)} = \frac{2 \sin \frac{1}{2} (p+q) \cos \frac{1}{2} (p-q)}{2 \sin \frac{1}{2} (p+q) \cos \frac{1}{2} (p+q)} = \frac{\cos \frac{1}{2} (p-q)}{\cos \frac{1}{2} (p+q)}$$

$$\frac{\sin p - \sin q}{\sin (p+q)} = \frac{2 \sin \frac{1}{2} (p-q) \cos \frac{1}{2} (p+q)}{2 \sin \frac{1}{2} (p+q) \cos \frac{1}{2} (p+q)} = \frac{\sin \frac{1}{2} (p-q)}{\sin \frac{1}{2} (p+q)}$$

Formulas which are the expression of so many theorems. From the first, it follows that the *sum of the sines of two arcs is to the difference of these sines, as the tangent of half the sum of the arcs is to the tangent of half their difference.*

XXV. In order likewise to develop some formulas relative to tangents, let us consider the expression

$\text{tang } (a+b) = \frac{R \sin (a+b)}{\cos (a+b)}$ , in which by substituting the values of  $\sin (a+b)$  and  $\cos (a+b)$ , we shall find

$$\text{tang } (a+b) = \frac{R (\sin a \cos b + \sin b \cos a)}{\cos a \cos b - \sin b \sin a}.$$

Now we have  $\sin a = \frac{\cos a \text{ tang } a}{R}$ , and  $\sin b = \frac{\cos b \text{ tang } b}{R}$ ; substitute these values, dividing all the terms by  $\cos a \cos b$ ; we shall have

$$\text{tang } (a+b) = \frac{R^2 (\text{tang } a + \text{tang } b)}{R^2 - \text{tang } a \text{ tang } b};$$

which is the value of the tangent of the sum of two arcs, expressed by the tangents of each of these arcs. For the tangent of their difference, we should in like manner find

$$\text{tang } (a-b) = \frac{R^2 (\text{tang } a - \text{tang } b)}{R^2 + \text{tang } a \text{ tang } b}.$$

Suppose  $b=a$ ; for the duplication of the arcs, we shall have the formula

$$\text{tang } 2a = \frac{2 R^2 \text{ tang } a}{R^2 - \text{tang}^2 a};$$

Suppose  $b=2a$ ; for their triplication, we shall have the formula

$$\text{tang } 3a = \frac{R^2 (\text{tang } a + \text{tang } 2a)}{R^2 - \text{tang } a \text{ tang } 2a};$$

in which, substituting the value of  $\text{tang } 2a$ , we shall have

$$\text{tang } 3a = \frac{3R^2 \text{ tang } a - \text{tang}^3 a}{R^2 - 3 \text{ tang}^2 a}.$$

XXVI. *Scholium.* The radius  $R$  being entirely arbitrary, is generally taken equal to 1, in which case it does not appear in the trigonometrical formulas. For example the expression for the tangent of twice an arc when  $R=1$ , becomes,

$$\text{tang } 2a = \frac{2 \text{ tang } a}{1 - \text{tang}^2 a}.$$

If we have an analytical formula calculated to the radius of 1, and wish to apply it to another circle in which the radius is  $R$ , we must multiply each term by such a power of  $R$  as will make all the terms homogeneous: that is, so that each shall contain the same number of literal factors.

## CONSTRUCTION AND DESCRIPTION OF THE TABLES.

XXVII. If the radius of a circle is taken equal to 1, and the lengths of the lines representing the sines, cosines, tangents, cotangents, &c. for every minute of the quadrant be calculated, and written in a table, this would be a table of *natural* sines, cosines, &c.

XXVIII. If such a table were known, it would be easy to calculate a table of sines, &c. to any other radius; since, in different circles, the sines, cosines, &c. of arcs containing the same number of degrees, are to each other as their radii.

XXIX. If the trigonometrical lines themselves were used, it would be necessary, in the calculations, to perform the operations of multiplication and division. To avoid so tedious a method of calculation, we use the logarithms of the sines, cosines, &c.; so that the tables in common use show the values of the logarithms of the sines, cosines, tangents, cotangents, &c. for each degree and minute of the quadrant, calculated to a given radius. This radius is 10,000,000,000, and consequently its logarithm is 10.

XXX. Let us glance for a moment at one of the methods of calculating a table of natural sines.

The radius of a circle being 1, the semi-circumference is known to be 3.14159265358979. This being divided successively, by 180 and 60, or at once by 10800, gives .0002908882086657, for the arc of 1 minute. Of so small an arc the sine, chord, and arc, differ almost imperceptibly from the ratio of equality; so that the first ten of the preceding figures, that is, .0002908882 may be regarded as the sine of 1'; and in fact the sine given in the tables which run to seven places of figures is .0002909. By Art. XVI. we have for any arc,  $\cos = \sqrt{1 - \sin^2}$ . This theorem gives, in the present case,  $\cos 1' = .9999999577$ . Then by Art. XXII. we shall have

$$2 \cos 1' \times \sin 1' - \sin 0' = \sin 2' = .0005817764$$

$$2 \cos 1' \times \sin 2' - \sin 1' = \sin 3' = .0008726646$$

$$2 \cos 1' \times \sin 3' - \sin 2' = \sin 4' = .0011635526$$

$$2 \cos 1' \times \sin 4' - \sin 3' = \sin 5' = .0014544407$$

$$2 \cos 1' \times \sin 5' - \sin 4' = \sin 6' = .0017453284$$

&amp;c.

&amp;c.

&amp;c.

Thus may the work be continued to any extent, the whole difficulty consisting in the multiplication of each successive result by the quantity  $2 \cos 1' = 1.9999999154$ .

Or, the sines of 1' and 2' being determined, the work might be continued thus (Art. XXI.):

$$\begin{array}{l} \sin 1' : \sin 2' - \sin 1' :: \sin 2' + \sin 1' : \sin 3' \\ \sin 2' : \sin 3' - \sin 1' :: \sin 3' + \sin 1' : \sin 4' \\ \sin 3' : \sin 4' - \sin 1' :: \sin 4' + \sin 1' : \sin 5' \\ \sin 4' : \sin 5' - \sin 1' :: \sin 5' + \sin 1' : \sin 6' \\ \quad \&c. \qquad \qquad \quad \&c. \qquad \qquad \quad \&c. \end{array}$$

In like manner, the computer might proceed for the sines of degrees, &c. thus :

$$\begin{array}{l} \sin 1^\circ : \sin 2^\circ - \sin 1^\circ :: \sin 2^\circ + \sin 1^\circ : \sin 3^\circ \\ \sin 2^\circ : \sin 3^\circ - \sin 1^\circ :: \sin 3^\circ + \sin 1^\circ : \sin 4^\circ \\ \sin 3^\circ : \sin 4^\circ - \sin 1^\circ :: \sin 4^\circ + \sin 1^\circ : \sin 5^\circ \\ \quad \&c. \qquad \qquad \quad \&c. \qquad \qquad \quad \&c. \end{array}$$

Above  $45^\circ$  the process may be considerably simplified by the theorem for the tangents of the sums and differences of arcs. For, when the radius is unity, the tangent of  $45^\circ$  is also unity, and  $\tan(a+b)$  will be denoted thus :

$$\tan(45^\circ + b) = \frac{1 + \tan b}{1 - \tan b}.$$

And this, again, may be still further simplified in practice. The secants and cosecants may be found from the cosines and sines.

#### TABLE OF LOGARITHMS.

XXXI. If the logarithms of all the numbers between 1 and any given number, be calculated and arranged in a tabular form, such table is called a table of logarithms. The table annexed shows the logarithms of all numbers between 1 and 10,000.

The first column, on the left of each page of the table, is the column of numbers, and is designated by the letter N; the decimal part of the logarithms of these numbers is placed directly opposite them, and on the same horizontal line.

The *characteristic* of the logarithm, or the part which stands to the left of the decimal point, is always known, being 1 less than the places of integer figures in the given number, and therefore it is not written in the table of logarithms. Thus, for all numbers between 1 and 10, the characteristic is 0: for numbers between 10 and 100 it is 1, between 100 and 1000 it is 2, &c.

## PROBLEM.

*To find from the table the logarithm of any number.*

## CASE I.

*When the number is less than 100.*

Look on the first page of the table of logarithms, along the columns of numbers under N, until the number is found ; the number directly opposite it, in the column designated Log., is the logarithm sought.

## CASE II.

*When the number is greater than 100, and less than 10,000.*

Find, in the column of numbers, the three first figures of the given number. Then, pass across the page, in a horizontal line, into the columns marked 0, 1, 2, 3, 4, &c., until you come to the column which is designated by the fourth figure of the given number : to the four figures so found, two figures taken from the column marked 0, are to be prefixed. If the four figures found, stand opposite to a row of six figures in the column marked 0, the two figures from this column, which are to be prefixed to the four before found, are the first two on the left hand ; but, if the four figures stand opposite a line of only four figures, you are then to ascend the column, till you come to the line of six figures : the two figures at the left hand are to be prefixed, and then the decimal part of the logarithm is obtained. To this, the characteristic of the logarithm is to be prefixed, which is always one less than the places of integer figures in the given number. Thus, the logarithm of 1122 is 3.049993.

In several of the columns, designated 0, 1, 2, 3, &c., small dots are found. Where this occurs, a cipher must be written for each of these dots, and the two figures which are to be prefixed, from the first column, are then found in the horizontal line directly below. Thus, the log. of 2188 is 3.340047, the two dots being changed into two ciphers, and the 34 from the column 0, prefixed. The two figures from the column 0, must also be taken from the line below, if any dots shall have been passed over, in passing along the horizontal line : thus, the logarithm of 3098 is 3.491081, the 49 from the column 0 being taken from the line 310.

## CASE III.

*When the number exceeds 10,000, or consists of five or more places of figures.*

Consider all the figures after the fourth from the left hand, as ciphers. Find, from the table, the logarithm of the first four places, and prefix a characteristic which shall be one less than the number of places including the ciphers. Take from the last column on the right of the page, marked D, the number on the same horizontal line with the logarithm, and multiply this number by the numbers that have been considered as ciphers: then, cut off from the right hand as many places for decimals as there are figures in the multiplier, and add the product, so obtained, to the first logarithm: this sum will be the logarithm sought.

Let it be required to find the logarithm of 672887. The log. of 672800 is found, on the 11th page of the table, to be 5.827886, after prefixing the characteristic 5. The corresponding number in the column D is 65, which being multiplied by 87, the figures regarded as ciphers, gives 5655; then, pointing off two places for decimals, the number to be added is 56.55. This number being added to 5.827886, gives 5.827942 for the logarithm of 672887; the decimal part .55, being omitted.

This method of finding the logarithms of numbers, from the table, supposes that the logarithms are proportional to their respective numbers, which is not rigorously true. In the example, the logarithm of 672800 is 5.827886; the logarithm of 672900, a number greater by 100, 5.827951: the difference of the logarithms is 65. Now, as 100, the difference of the numbers, is to 65, the difference of their logarithms, so is 87, the difference between the given number and the least of the numbers used, to the difference of their logarithms, which is 56.55: this difference being added to 5.827886, the logarithm of the less number, gives 5.827942 for the logarithm of 672887. The use of the column of differences is therefore manifest.

When, however, the decimal part which is to be omitted exceeds .5, we come nearer to the true result by increasing the next figure to the left by 1; and this will be done in all the calculations which follow. Thus, the difference to be added, was nearer 57 than 56; hence it would have been more exact to have added the former number.

The logarithm of a vulgar fraction is equal to the logarithm of the numerator, minus the logarithm of the denom-

inator. The logarithm of a decimal fraction is found, *by considering it as a whole number, and then prefixing to the decimal part of its logarithm a negative characteristic, greater by unity than the number of ciphers between the decimal point and the first significant place of figures.* Thus, the logarithm of .0412, is 2.614897.

PROBLEM.

*To find from the table, a number answering to a given logarithm.*

XXXII Search, in the column of logarithms, for the decimal part of the given logarithm, and if it be exactly found, set down the corresponding number. Then, if the characteristic of the given logarithm be positive, point off, from the left of the number found, one place more for whole numbers than there are units in the characteristic of the given logarithm, and treat the other places as decimals; this will give the number sought.

If the characteristic of the given logarithm be 0, there will be one place of whole numbers; if it be  $-1$ , the number will be entirely decimal; if it be  $-2$ , there will be one cipher between the decimal point and the first significant figure; if it be  $-3$ , there will be two, &c. The number whose logarithm is 1.492481 is found in page 5, and is 31.08.

But if the decimal part of the logarithm cannot be exactly found in the table, take the number answering to the nearest less logarithm; take also from the table the corresponding difference in the column D: then, subtract this less logarithm from the given logarithm; and having annexed a sufficient number of ciphers to the remainder, divide it by the difference taken from the column D, and annex the quotient to the number answering to the less logarithm: this gives the required number, nearly. This rule, like the one for finding the logarithm of a number when the places exceed four, supposes the numbers to be proportional to their corresponding logarithms.

*Ex. 1.* Find the number answering to the logarithm 1.532708. Here,

|                                  |   |   |   |           |
|----------------------------------|---|---|---|-----------|
| The given logarithm, is          | - | - | - | 1.532708  |
| Next less logarithm of 34,09, is | - | - | - | 1.532627  |
| Their difference is              | - | - | - | <u>81</u> |

And the tabular difference is 128: hence

128) 81.00 (63

which being annexed to 34,09, gives 34.0963 for the number answering to the logarithm 1.532708.

*Ex. 2.* Required the number answering to the logarithm 3.233568.

|   |  |
|---|--|
| The given logarithm is                      | 3.233568   |
| The next less tabular logarithm of 1712, is | 3.233504   |
|   | Diff. = <span style="border-top: 1px solid black; border-bottom: 1px solid black;">64</span> |

Tab. Diff. = 253) 64.00 (25

Hence the number sought is 1712.25, marking four places of integers for the characteristic 3.

### TABLE OF LOGARITHMIC SINES.

XXXIII. In this table are arranged the logarithms of the numerical values of the sines, cosines, tangents, and cotangents, of all the arcs or angles of the quadrant, divided to minutes, and calculated for a radius of 10,000,000,000. The logarithm of this radius is 10. In the first and last horizontal line, of each page, are written the degrees whose logarithmic sines, &c. are expressed on the page. The vertical columns on the left and right, are columns of minutes.

#### CASE I.

*To find, in the table, the logarithmic sine, cosine, tangent, or cotangent of any given arc or angle.*

1. If the angle be less than  $45^\circ$ , look in the first horizontal line of the different pages, until the number of degrees be found; then descend along the column of minutes, on the left of the page, till you reach the number showing the minutes; then pass along the horizontal line till you come into the column designated, *sine*, *cosine*, *tangent*, or *cotangent*, as the case may be: the number so indicated, is the logarithm sought. Thus, the sine, cosine, tangent, and cotangent of  $19^\circ 55'$ , are found on page 37, opposite 55, and are, respectively, 9.532312, 9.973215, 9.559097, 10.440903.

2. If the angle be greater than  $45^\circ$ , search along the bottom line of the different pages, till the number of degrees are found; then ascend along the column of minutes, on the right hand side of the page, till you reach the number expressing the minutes; then pass along the horizontal line into the columns designated *tang.*, *cotang.*, *sine*, *cosine*, as the case may be: the number so pointed out is the logarithm required.

It will be seen, that the column designated sine at the top of the page, is designated cosine at the bottom ; the one designated tang., by cotang., and the one designated cotang., by tang.

The angle found by taking the degrees at the top of the page, and the minutes from the first vertical column on the left, is the complement of the angle, found by taking the corresponding degrees at the bottom of the page, and the minutes traced up in the right hand column to the same horizontal line. This being apparent, the reason is manifest, why the columns designated sine, cosine, tang., and cotang., when the degrees are pointed out at the top of the page, and the minutes counted downwards, ought to be changed, respectively, into cosine, sine, cotang., and tang., when the degrees are shown at the bottom of the page, and the minutes counted upwards.

If the angle be greater than  $90^\circ$ , we have only to subtract it from  $180^\circ$ , and take the sine, cosine, tangent, or cotangent of the remainder.

The secants and cosecants are omitted in the table, being easily found from the cosines and sines.

For,  $\sec. = \frac{R^2}{\cos.}$  ; or, taking the logarithms,  $\log. \sec. = 2$

$\log. R - \log. \cos. = 20 - \log. \cos.$  ; that is, *the logarithmic secant is found by subtracting the logarithmic cosine from 20.* And

$\csc. = \frac{R^2}{\sin.}$ , or  $\log. \csc. = 2 \log. R - \log. \sin. = 20 - \log.$

$\sin.$  ; that is, *the logarithmic cosecant is found by subtracting the logarithmic sine from 20.*

It has been shown that  $R^2 = \text{tang.} \times \text{cotang.}$  ; therefore,  $2 \log. R = \log. \text{tang.} + \log. \text{cotang.}$  ; or  $20 = \log. \text{tang.} + \log. \text{cotang.}$

The column of the table, next to the column of sines, and on the right of it, is designated by the letter D. This column is calculated in the following manner. Opening the table at any page, as 42, the sine of  $24^\circ$  is found to be 9.609313 ; of  $24^\circ 1'$ , 9.609597 : their difference is 284 ; this being divided by 60, the number of seconds in a minute, gives 4.73, which is entered in the column D, omitting the decimal point. Now, supposing the increase of the logarithmic sine to be proportional to the increase of the arc, and it is nearly so for  $60''$ , it follows, that 473 (the last two places being regarded as decimals) is the increase of the sine for  $1''$ . Similarly, if the arc be  $24^\circ 20'$ , the increase of the sine for  $1''$ , is 465, the last two places being decimals. The same remarks are equally applicable in respect of the column D, after the column cosine, and of the column D, between the tangents and cotangents. The column D between the tangents and cotangents, answers

to either of these columns; since of the same arc, the  $\log. \text{tang.} + \log. \text{cotang.} = 20$ . Therefore, having two arcs,  $a$  and  $b$ ,  $\log. \text{tang. } b + \log. \text{cotang. } b = \log. \text{tang. } a + \log. \text{cotang. } a$ ; or,  $\log. \text{tang. } b - \log. \text{tang. } a = \log. \text{cotang. } a - \log. \text{cotang. } b$ .

Now, if it were required to find the logarithmic sine of an arc expressed in degrees, minutes, and seconds, we have only to find the degrees and minutes as before; then multiply the corresponding tabular number by the seconds, cut off two places to the right hand for decimals, and then add the product to the number first found, for the sine of the given arc. Thus, if we wish the sine of  $40^\circ 26' 28''$ .

The sine  $40^\circ 26'$       -      -      -      -      9.811952      -

Tabular difference = 247

Number of seconds = 28

Product = 69.16, to be added      =      69.16

Gives for the sine of  $40^\circ 26' 28'' = 9.812021.16$

The tangent of an arc, in which there are seconds, is found in a manner entirely similar. In regard to the cosine and cotangent, it must be remembered, that they increase while the arcs decrease, and decrease while the arcs are increased, consequently, the proportional numbers found for the seconds must be subtracted, not added.

*Ex.* To find the cosine  $3^\circ 40' 40''$ .

Cosine  $3^\circ 40'$       9.999110

Tabular difference = 13

Number of seconds = 40

Product = 5.20, which being subtracted      =      5.20

Gives for the cosine of  $3^\circ 40' 40'' = 9.999104.80$

## CASE II.

*To find the degrees, minutes, and seconds answering to any given logarithmic sine, cosine, tangent, or cotangent.*

Search in the table, and in the proper column, until the number be found; the degrees are shown either at the top or bottom of the page, and the minutes in the side columns, either at the left or right. But if the number cannot be exactly found in the table, take the degrees and minutes answering to the nearest less logarithm, the logarithm itself, and also the corresponding tabular difference. Subtract the logarithm taken, from the

given logarithm, annex two ciphers, and then divide the remainder by the tabular difference : the quotient is seconds, and is to be connected with the degrees and minutes before found ; to be added for the sine and tangent, and subtracted for the cosine and cotangent.

*Ex. 1.* To find the arc answering to the sine 9.880054  
Sine  $49^{\circ} 20'$ , next less in the table, 9.879963

Tab. Diff. 181)9100(50"

Hence the arc  $49^{\circ} 20' 50''$  corresponds to the given sine 9.880054.

*Ex. 2.* To find the arc corresponding to cotang. 10.008688.  
Cotang  $44^{\circ} 26'$ , next less in the table 10.008591

Tab. Diff. 421)9700(23"

Hence,  $44^{\circ} 26' - 23'' = 44^{\circ} 25' 37''$  is the arc corresponding to the given cotangent 10.008688.

## PRINCIPLES FOR THE SOLUTION OF RECTILINEAL TRIANGLES.

### THEOREM I.

*In every right angled triangle, radius is to the sine of either of the acute angles, as the hypotenuse to the opposite side : and radius is to the cosine of either of the acute angles, as the hypotenuse to the adjacent side.*

Let ABC be the proposed triangle, right-angled at A : from the point C as a centre, with a radius CD equal to the radius of the tables, describe the arc DE, which will measure the angle C ; on CD let fall the perpendicular EF, which will be the sine of the angle C, and CF will be its cosine. The triangles CBA, CEF, are similar, and give the proportion,

$$\begin{aligned} \text{CE} : \text{EF} &:: \text{CB} : \text{BA} : \text{hence} \\ \text{R} : \sin C &:: \text{BC} : \text{BA}. \end{aligned}$$

But we also have,

$$\begin{aligned} CE : CF &:: CB : CA : \text{hence} \\ R : \cos C &:: CB : CA. \end{aligned}$$

*Cor.* If the radius  $R=1$ , we shall have,

$$AB = CB \sin C, \text{ and } CA = CB \cos C.$$

Hence, in every right angled triangle, *the perpendicular is equal to the hypotenuse multiplied by the sine of the angle at the base ; and the base is equal to the hypotenuse multiplied by the cosine of the angle at the base ; the radius being equal to unity.*

### THEOREM II.

*In every right angled triangle, radius is to the tangent of either of the acute angles, as the side adjacent to the side opposite.*

Let  $CAB$  be the proposed triangle.

With any radius, as  $CD$ , describe the arc  $DE$ , and draw the tangent  $DG$ .

From the similar triangles  $CDG$ ,  $CAB$ , we shall have,

$$\begin{aligned} CD : DG &:: CA : AB : \text{hence,} \\ R : \tan C &:: CA : AB. \end{aligned}$$

*Cor. 1.* If the radius  $R=1$ ,  
 $AB = CA \tan C$ .

Hence, *the perpendicular of a right angled triangle is equal to the base multiplied by the tangent of the angle at the base, the radius being unity.*

*Cor. 2.* Since the tangent of an arc is equal to the cotangent of its complement (Art. VI.), the cotangent of  $B$  may be substituted in the proportion for  $\tan C$ , which will give

$$R : \cot B :: CA : AB.$$

### THEOREM III.

*In every rectilineal triangle, the sines of the angles are to each other as the opposite sides.*

Let  $ABC$  be the proposed triangle ;  $AD$  the perpendicular, let fall from the vertex  $A$  on the opposite side  $BC$  : there may be two cases.

*First.* If the perpendicular falls within the triangle  $ABC$ , the right-angled triangles  $ABD$ ,  $ACD$ , will give,

$$R : \sin B :: AB : AD.$$

$$R : \sin C :: AC : AD.$$

In these two propositions, the extremes are equal ; hence,

$$\sin C : \sin B :: AB : AC.$$

*Secondly.* If the perpendicular falls without the triangle  $ABC$ , the right-angled triangles  $ABD$ ,  $ACD$ , will still give the proportions,

$$R : \sin ABD :: AB : AD,$$

$$R : \sin C :: AC : AD;$$

from which we derive

$$\sin C : \sin ABD :: AB : AC.$$

But the angle  $ABD$  is the supplement of  $ABC$ , or  $B$  ; hence  $\sin ABD = \sin B$  ; hence we still have

$$\sin C : \sin B :: AB : AC.$$

#### THEOREM IV.

*In every rectilineal triangle, the cosine of either of the angles is equal to radius multiplied by the sum of the squares of the sides adjacent to the angle, minus the square of the side opposite, divided by twice the rectangle of the adjacent sides.*

Let  $ABC$  be a triangle : then will

$$\cos B = R \frac{AB^2 + BC^2 - AC^2}{2AB \times BC}.$$

*First.* If the perpendicular falls within the triangle, we shall have  $AC^2 = AB^2 + BC^2 - 2BC \times BD$  (Book IV. Prop. XII.) ;

hence  $BD = \frac{AB^2 + BC^2 - AC^2}{2BC}$ . But in the right-angled triangle

$ABD$ , we have

$$R : \cos B :: AB : BD ;$$

hence,  $\cos B = \frac{R \times BD}{AB}$ , or by substituting the value of BD,

$$\cos B = R \times \frac{AB^2 + BC^2 - AC^2}{2AB \times BC}$$

*Secondly.* If the perpendicular falls without the triangle, we shall have  $AC^2 = AB^2 + BC^2 + 2BC \times BD$ ; hence

$$BD = \frac{AC^2 - AB^2 - BC^2}{2BC}.$$

But in the right-angled triangle BAD,

we still have  $\cos ABD = \frac{R \times BD}{AB}$ ; and the angle ABD being supplemental to ABC, or B, we have

$$\cos B = -\cos ABD = -\frac{R \times BD}{AB}.$$

hence by substituting the value of BD, we shall again have

$$\cos B = R \times \frac{AB^2 + BC^2 - AC^2}{2AB \times BC}.$$

*Scholium.* Let A, B, C, be the three angles of any triangle;  $a, b, c$ , the sides respectively opposite them: by the theorem, we shall have  $\cos B = R \times \frac{a^2 + c^2 - b^2}{2ac}$ . And the same principle,

when applied to each of the other two angles, will, in like manner give  $\cos A = R \times \frac{b^2 + c^2 - a^2}{2bc}$ , and  $\cos C = R \times \frac{a^2 + b^2 - c^2}{2ab}$ .

Either of these formulas may readily be reduced to one in which the computation can be made by logarithms.

Recurring to the formula  $R^2 - R \cos A = 2 \sin^2 \frac{1}{2} A$  (Art. XXIII.), or  $2 \sin^2 \frac{1}{2} A = R^2 - R \cos A$ , and substituting for  $\cos A$ , we shall have

$$\begin{aligned} 2 \sin^2 \frac{1}{2} A &= R^2 - R^2 \times \frac{b^2 + c^2 - a^2}{2bc} \\ &= \frac{R^2 \times 2bc - R^2(b^2 + c^2 - a^2)}{2bc} = R^2 \times \frac{a^2 - b^2 - c^2 + 2bc}{2bc} \\ &= R^2 \times \frac{a^2 - (b - c)^2}{2bc} = R^2 \times \frac{(a + b - c)(a + c - b)}{2bc}. \quad \text{Hence} \\ \sin \frac{1}{2} A &= R \sqrt{\frac{(a + b - c)(a + c - b)}{4bc}}. \end{aligned}$$

For the sake of brevity, put

$\frac{1}{2}(a + b + c) = p$ , or  $a + b + c = 2p$ ; we have  $a + b - c = 2p - 2c$ ,  $a + c - b = 2p - 2b$ ; hence

$$\sin \frac{1}{2} A = R \sqrt{\frac{(p - b)(p - c)}{bc}}.$$

## THEOREM V.

*In every rectilineal triangle, the sum of two sides is to their difference as the tangent of half the sum of the angles opposite those sides, to the tangent of half their difference.*

For.  $AB : BC :: \sin C : \sin A$  (Theorem III.). Hence,  $AB + BC : AB - BC :: \sin C + \sin A : \sin C - \sin A$ . But

$$\sin C + \sin A : \sin C - \sin A :: \tan \frac{C + A}{2} :$$

$$\tan \frac{C - A}{2} \text{ (Art. XXIV.) ; hence,}$$

$$AB + BC : AB - BC :: \tan \frac{C + A}{2} : \tan \frac{C - A}{2}, \text{ which is}$$

the property we had to demonstrate.

With the aid of these five theorems we can solve all the cases of rectilineal trigonometry.

*Scholium.* The required part should always be found from the given parts ; so that if an error is made in any part of the work, it may not affect the correctness of that which follows.

### SOLUTION OF RECTILINEAL TRIANGLES BY MEANS OF LOGARITHMS.

It has already been remarked, that in order to abridge the calculations which are necessary to find the unknown parts of a triangle, we use the logarithms of the parts instead of the parts themselves.

Since the addition of logarithms answers to the multiplication of their corresponding numbers, and their subtraction to the division of their numbers ; it follows, that the logarithm of the fourth term of a proportion will be equal to the sum of the logarithms of the second and third terms, diminished by the logarithm of the first term.

Instead, however, of subtracting the logarithm of the first term from the sum of the logarithms of the second and third terms, it is more convenient to use the *arithmetical complement* of the first term.

The *arithmetical complement* of a logarithm is the number which remains after subtracting the logarithm from 10. Thus  $10 - 9.274687 = 0.725313$  : hence, 0.725313 is the arithmetical complement of 9.274687.

It is now to be shown that, *the difference between two logarithms is truly found, by adding to the first logarithm the arithmetical complement of the logarithm to be subtracted, and diminishing their sum by 10.*

Let  $a$  = the first logarithm.  
 $b$  = the logarithm to be subtracted.  
 $c = 10 - b$  = the arithmetical complement of  $b$ .

Now, the difference between the two logarithms will be expressed by  $a - b$ . But from the equation  $c = 10 - b$ , we have  $c - 10 = -b$ : hence if we substitute for  $-b$  its value, we shall have

$$a - b = a + c - 10,$$

which agrees with the enunciation.

When we wish the arithmetical complement of a logarithm, we may write it directly from the tables, by subtracting the left hand figure from 9, then proceeding to the right, subtract each figure from 9, till we reach the last significant figure, which must be taken from 10: this will be the same as taking the logarithm from 10.

*Ex.* From 3.274107 take 2.104729.

*Common method.*

3.274107  
 2.104729  
 —————

Diff. 1.169378

*By ar.-comp.*

3.274107  
 ar.-comp. 7.895271  
 —————

sum 1.169378 after re-

jecting the 10.

We therefore have, for all the proportions of trigonometry, the following

#### RULE.

*Add together the arithmetical complement of the logarithm of the first term, the logarithm of the second term, and the logarithm of the third term, and their sum after rejecting 10, will be the logarithm of the fourth term. And if any expression occurs in which the arithmetical complement is twice used, 20 must be rejected from the sum.*

SOLUTION OF RIGHT ANGLED TRIANGLES.

Let A be the right angle of the proposed right angled triangle, B and C the other two angles; let  $a$  be the hypotenuse,  $b$  the side opposite the angle B,  $c$  the side opposite the angle C. Here we must consider that the two angles C and B are complements of each other; and that consequently, according to the different cases, we are entitled to assume  $\sin C = \cos B$ ,  $\sin B = \cos C$ , and likewise  $\tan B = \cot C$ ,  $\tan C = \cot B$ . This being fixed, the unknown parts of a right angled triangle may be found by the first two theorems; or if two of the sides are given, by means of the property, that the square of the hypotenuse is equal to the sum of the squares of the other two sides.

EXAMPLES.

*Ex. 1.* In the right angled triangle BCA, there are given the hypotenuse  $a=250$ , and the side  $b=240$ ; required the other parts.

$$\begin{array}{l} R : \sin B :: a : b \text{ (Theorem I.)} \\ \text{or,} \quad a : b :: R : \sin B. \end{array}$$

When logarithms are used, it is most convenient to write the proportion thus,

|             |   |                     |   |                      |      |   |                 |
|-------------|---|---------------------|---|----------------------|------|---|-----------------|
| As hyp. $a$ | - | 250                 | - | ar.-comp.            | log. | - | 7.602060        |
| To side $b$ | - | 240                 | - | -                    | -    | - | 2.380211        |
| So is $R$   | - | -                   | - | -                    | -    | - | 10.000000       |
| To $\sin B$ | - | $73^\circ 44' 23''$ | - | (after rejecting 10) |      |   | <u>9.982271</u> |

But the angle  $C=90^\circ-B=90^\circ-73^\circ 44' 23''=16^\circ 15' 37''$  or, C might be found by the proportion,

|             |   |                     |   |           |      |   |                 |
|-------------|---|---------------------|---|-----------|------|---|-----------------|
| As hyp. $a$ | - | 250                 | - | ar.-comp. | log. | - | 7.602060        |
| To side $b$ | - | 240                 | - | -         | -    | - | 2.380211        |
| So is $R$   | - | -                   | - | -         | -    | - | 10.000000       |
| To $\cos C$ | - | $16^\circ 15' 37''$ | - | -         | -    | - | <u>9.982271</u> |

To find the side  $c$ , we say,

|                |                     |   |   |           |      |   |                 |
|----------------|---------------------|---|---|-----------|------|---|-----------------|
| As $R$         | -                   | - | - | ar. comp. | log. | - | 0.000000        |
| To $\tan C$    | $16^\circ 15' 37''$ | - | - | -         | -    | - | 9.464889        |
| So is side $b$ | 240                 | - | - | -         | -    | - | 2.380211        |
| To side $c$    | 70.0003             | - | - | -         | -    | - | <u>1.845100</u> |

Or the side  $c$  might be found from the equation

$$a^2 = b^2 + c^2.$$

For,

$$c^2 = a^2 - b^2 = (a + b) \times (a - b) :$$

hence,

$$2 \log. c = \log. (a + b) + \log. (a - b), \text{ or}$$

$$\log. c = \frac{1}{2} \log. (a + b) + \frac{1}{2} \log. (a - b)$$

$$a + b = 250 + 240 = 490 \quad \log. \quad 2.690196$$

$$a - b = 250 - 240 = 10 \quad - \quad - \quad 1.000000$$

$$2) \quad 3.690196$$

$$\log. c \quad 70 \quad - \quad - \quad - \quad - \quad - \quad - \quad \underline{1.845098}$$

*Ex. 2.* In the right angled triangle BCA, there are given, side  $b = 384$  yards, and the angle  $B = 53^\circ 8'$ : required the other parts.

To find the third side  $c$ .

$$R : \tan B :: c : b \text{ (Theorem II.)}$$

$$\text{or,} \quad \tan B : R :: b : c. \text{ Hence,}$$

|                |               |           |         |                 |
|----------------|---------------|-----------|---------|-----------------|
| As $\tan B$    | $53^\circ 8'$ | ar.-comp. | $\log.$ | 9.875010        |
| Is to          | R             | -         | -       | 10.000000       |
| So is side $b$ | 384           | -         | -       | 2.584331        |
| To side        | $c$           | -         | -       | <u>2.459341</u> |

*Note.* When the logarithm whose arithmetical complement is to be used, exceeds 10, take the arithmetical complement with reference to 20 and reject 20 from the sum.

To find the hypotenuse  $a$ .

$$R : \sin B :: a : b \text{ (Theorem I.). Hence,}$$

|                |               |           |         |                 |
|----------------|---------------|-----------|---------|-----------------|
| As $\sin B$    | $53^\circ 8'$ | ar. comp. | $\log.$ | 0.096892        |
| Is to          | R             | -         | -       | 10.000000       |
| So is side $b$ | 384           | -         | -       | 2.584331        |
| To hyp.        | $a$           | -         | -       | <u>2.681223</u> |

*Ex. 3.* In the right angled triangle BAC, there are given, side  $c = 195$ , angle  $B = 47^\circ 55'$ , required the other parts.

$$\text{Ans. Angle } C = 42^\circ 05', a = 290.953, b = 215.937.$$

#### SOLUTION OF RECTILINEAL TRIANGLES IN GENERAL.

Let  $A, B, C$  be the three angles of a proposed rectilineal triangle;  $a, b, c$ , the sides which are respectively opposite them; the different problems which may occur in determining three of these quantities by means of the other three, will all be reducible to the four following cases.

CASE I.

*Given a side and two angles of a triangle, to find the remaining parts.*

First, subtract the sum of the two angles from two right angles, the remainder will be the third angle. The remaining sides can then be found by Theorem III.

I. In the triangle ABC, there are given the angle  $A=58^{\circ} 07'$ , the angle  $B=22^{\circ} 37'$ , and the side  $c=408$  yards: required the remaining angle and the two other sides.

|   |   |   |   |   |   |                   |
|---|---|---|---|---|---|-------------------|
| To the angle A                              | - | - | - | - | - | $=58^{\circ} 07'$ |
| Add the angle B                             | - | - | - | - | - | $=22^{\circ} 37'$ |
| Their sum                                   | - | - | - | - | - | $=80^{\circ} 44'$ |
| taken from $180^{\circ}$ leaves the angle C | - | - | - | - | - | $=99^{\circ} 16'$ |

This angle being greater than  $90^{\circ}$  its sine is found by taking that of its supplement  $80^{\circ} 44'$ .

To find the side  $a$ .

|                |                  |           |      |                 |

| To side $AB'$ 281.785                  | -         | -    | <u>2.449918</u> |

The ambiguity in this, and similar examples, arises in consequence of the first proportion being true for both the triangles  $ACB$ ,  $ACB'$ . As long as the two triangles exist, the ambiguity will continue. But if the side  $CB$ , opposite the given angle, be greater than  $AC$ , the arc  $BB'$  will cut the line  $ABB'$ , on the same side of the point  $A$ , but in one point, and then there will be but one triangle answering the conditions.

If the side  $CB$  be equal to the perpendicular  $Cd$ , the arc  $BB'$  will be tangent to  $ABB'$ , and in this case also, there will be but one triangle. When  $CB$  is less than the perpendicular  $Cd$ , the arc  $BB'$  will not intersect the base  $ABB'$ , and in that case there will be no triangle, or the conditions are impossible.

2. Given two sides of a triangle 50 and 40 respectively, and the angle opposite the latter equal to  $32^\circ$ : required the remaining parts of the triangle.

Ans. If the angle opposite the side 50 be acute, it is equal to  $41^\circ 28' 59''$ , the third angle is then equal to  $106^\circ 31' 01''$ , and the third side to 72.368. If the angle opposite the side 50 be obtuse, it is equal to  $138^\circ 31' 01''$ , the third angle to  $9^\circ 28' 59''$ , and the remaining side to 12.436.

CASE III.

*Given two sides of a triangle, with their included angle, to find the third side and the two remaining angles.*

Let ABC be a triangle, B the given angle, and  $c$  and  $a$  the given sides.

Knowing the angle B, we shall likewise know the sum of the other two angles  $C + A = 180^\circ - B$ , and their half sum  $\frac{1}{2}(C + A) = 90^\circ - \frac{1}{2}B$ . We shall next compute the half difference of these two angles by the proportion (Theorem V.),

$$c + a : c - a :: \tan \frac{1}{2}(C + A) \text{ or } \cot \frac{1}{2}B : \tan \frac{1}{2}(C - A),$$

in which we consider  $c > a$  and consequently  $C > A$ . Having found the half difference, by adding it to the half sum  $\frac{1}{2}(C + A)$ , we shall have the greater angle C; and by subtracting it from the half-sum, we shall have the smaller angle A. For, C and A being any two quantities, we have always,

$$C = \frac{1}{2}(C + A) + \frac{1}{2}(C - A)$$

$$A = \frac{1}{2}(C + A) - \frac{1}{2}(C - A).$$

Knowing the angles C and A to find the third side  $b$ , we have the proportion.

$$\sin A : \sin B :: a : b$$

*Ex. 1.* In the triangle ABC, let  $a = 450$ ,  $c = 540$ , and the included angle  $B = 80^\circ$ : required the remaining parts.

$$c + a = 990, c - a = 90, 180^\circ - B = 100^\circ = C + A.$$

|                                 |               |           |      |                 |
|---------------------------------|---------------|-----------|------|-----------------|
| As $c + a$                      | 990           | ar.-comp. | log. | 7.004365        |
| Is to $c - a$                   | 90            | -         | -    | 1.954243        |
| So is $\tan \frac{1}{2}(C + A)$ | $50^\circ$    | -         | -    | 10.076187       |
| To $\tan \frac{1}{2}(C - A)$    | $6^\circ 11'$ | -         | -    | <u>9.034795</u> |

Hence,  $50^\circ + 6^\circ 11' = 56^\circ 11' = C$ ; and  $50^\circ - 6^\circ 11' = 43^\circ 49' = A$ .

To find the third side  $b$ .

|                |                |           |      |                 |
|----------------|----------------|-----------|------|-----------------|
| As $\sin A$    | $43^\circ 49'$ | ar.-comp. | log. | 0.159672        |
| Is to $\sin B$ | $80^\circ$     | -         | -    | 9.993351        |
| So is side $a$ | 450            | -         | -    | <u>2.653213</u> |
| To side $b$    | 640.082        | -         | -    | 2.806236        |

*Ex. 2.* Given two sides of a plane triangle, 1686 and 960, and their included angle  $128^\circ 04'$ : required the other parts.

*Ans.* Angles,  $33^\circ 34' 39''$ ,  $18^\circ 21' 21''$  side 2400

## CASE IV.

*Given the three sides of a triangle, to find the angles.*

We have from Theorem IV. the formula,

$$\sin \frac{1}{2} A = R \sqrt{\left( \frac{(p-b)(p-c)}{bc} \right)} \quad \text{in which}$$

$p$  represents the half sum of the three sides. Hence

$$\sin^2 \frac{1}{2} A = R^2 \left( \frac{(p-b)(p-c)}{bc} \right), \quad \text{or}$$

$$2 \log. \sin \frac{1}{2} A = 2 \log. R + \log. (p-b) + \log. (p-c) - \log. c - \log. b.$$

*Ex. 1.* In a triangle ABC, let  $b=40$ ,  $c=34$ , and  $a=25$ : required the angles.

$$\text{Here } p = \frac{40 + 34 + 25}{2} = 49.5, \quad p-b=9.5, \quad \text{and } p-c=15.5.$$

|                             |                     |   |           |   |   |                  |
|-----------------------------|---------------------|---|-----------|---|---|------------------|
| 2 Log. R                    | -                   | - | -         | - | - | 20.000000        |
| log. ( $p-b$ )              | 9.5                 | - | -         | - | - | 0.977724         |
| log. ( $p-c$ )              | 15.5                | - | -         | - | - | 1.190332         |
| —log. $c$                   | 34                  |   | ar.-comp. | - | - | 8.468521         |
| —log. $b$                   | 40                  |   | ar.-comp. | - | - | 8.397940         |
| 2 log. $\sin \frac{1}{2} A$ | -                   | - | -         | - | - | <u>19.034517</u> |
| log. $\sin \frac{1}{2} A$   | $19^\circ 12' 39''$ | - | -         | - | - | <u>9.517258</u>  |

Angle  $A = 38^\circ 25' 18''$ .

In a similar manner we find the angle  $B = 83^\circ 53' 18''$  and the angle  $C = 57^\circ 41' 24''$ .

*Ex. 2.* What are the angles of a plane triangle whose sides are,  $a=60$ ,  $b=50$ , and  $c=40$ ?

*Ans.*  $41^\circ 24' 34''$ ,  $55^\circ 46' 16''$  and  $82^\circ 49' 10''$ .

## APPLICATIONS.

Suppose the height of a building AB were required, the foot of it being accessible.

On the ground which we suppose to be horizontal or very nearly so, measure a base AD, neither very great nor very small in comparison with the altitude AB; then at D place the foot of the circle, or whatever be the instrument, with which we are to measure the angle BCE formed by the horizontal line CE parallel to AD, and by the visual ray direct it to the summit of the building. Suppose we find AD or CE=67.84 yards, and the angle BCE=41° 04': in order to find BE, we shall have to solve the right angled triangle BCE, in which the angle C and the adjacent side CE are known.

To find the side EB.

|               |         |   |   |   |   |   |   |           |   |                 |
|---------------|---------|---|---|---|---|---|---|-----------|---|-----------------|
| As R          | -       | - | - | - | - | - | - | ar.-comp. | - | 0.000000        |
| Is to tang. C | 41° 04' | - | - | - | - | - | - | -         | - | 9.940183        |
| So is EC      | 67.84   | - | - | - | - | - | - | -         | - | 1.831486        |
| To EB         | 59.111  | - | - | - | - | - | - | -         | - | <u>1.771669</u> |

Hence, EB=59.111 yards. To EB add the height of the instrument, which we will suppose to be 1.12 yards, we shall then have the required height AB=60.231 yards.

If, in the same triangle BCE it were required to find the hypotenuse, form the proportion

|          |         |           |   |   |      |                 |
|----------|---------|-----------|---|---|------|-----------------|
| As cos C | 41° 04' | ar.-comp. | - | - | log. | 0.122660        |
| Is to R  | -       | -         | - | - | -    | 10.000000       |
| So is CE | 67.84   | -         | - | - | -    | 1.831486        |
| To CB    | 89.98   | -         | - | - | -    | <u>1.954146</u> |

*Note.* If only the summit B of the building or place whose height is required were visible, we should determine the distance CE by the method shown in the following example; this distance and the given angle BCE are sufficient for solving the right angled triangle BCE, whose side, increased by the height of the instrument, will be the height required.

2. To find upon the ground the distance of the point A from an inaccessible object B, we must measure a base AD, and the two adjacent angles BAD, ADB. Suppose we have found  $AD = 588.45$  yards,  $BAD = 103^\circ 55' 55''$ , and  $BDA = 36^\circ 04'$ ; we shall thence get the third angle  $ABD = 40^\circ 05''$ , and to obtain AB, we shall form the proportion

|               |                 |           |        |   |                 |
|---------------|-----------------|-----------|--------|---|-----------------|
| As sine ABD   | $40^\circ 05''$ | ar.-comp. | - log. | - | 0.191920        |
| Is to sin BDA | $36^\circ 04'$  | -         | -      | - | 9.769913        |
| So is AD      | 588.45          | -         | -      | - | 2.769710        |
| To AB         | - - 538.943     | -         | -      | - | <u>2.731543</u> |

If for another inaccessible object C, we have found the angles  $CAD = 35^\circ 15'$ ,  $ADC = 119^\circ 32'$ , we shall in like manner find the distance  $AC = 1201.744$  yards.

3. To find the distance between two inaccessible objects B and C, we determine AB and AC as in the last example; we shall, at the same time, have the included angle  $BAC = BAD - DAC$ . Suppose AB has been found equal to 538.818 yards,  $AC = 1201.744$  yards, and the angle  $BAC = 68^\circ 40' 55''$ ; to get BC, we must resolve the triangle BAC, in which are known two sides and the included angle.

|                             |                     |           |      |   |                 |
|-----------------------------|---------------------|-----------|------|---|-----------------|
| As AC + AB                  | 1740.562            | ar.-comp. | log. | - | 6.759311        |
| Is to AC - AB               | 662.926             | -         | -    | - | 2.821465        |
| So is tang. $\frac{B+C}{2}$ | $55^\circ 39' 32''$ | -         | -    | - | 10.165449       |
| To tang. $\frac{B-C}{2}$    | $29^\circ 08' 19''$ | -         | -    | - | <u>9.746225</u> |

$$\text{Hence} \quad - \quad - \quad - \quad - \quad - \quad \frac{B-C}{2} = 29^\circ 08' 19''$$

$$\text{But we have} \quad - \quad - \quad - \quad - \quad - \quad \frac{B+C}{2} = 55^\circ 39' 32''$$

$$\text{Hence} \quad - \quad - \quad - \quad - \quad - \quad B = 84^\circ 47' 51''$$

$$\text{and} \quad - \quad - \quad - \quad - \quad - \quad C = 26^\circ 31' 13''$$

Now, to find the distance BC make the proportion,

|                                    |           |   |      |   |                 |
|------------------------------------|-----------|---|------|---|-----------------|
| As sine B $84^{\circ} 47' 51''$    | ar.-comp. | - | log. | - | 0.001793        |
| Is to sine A $68^{\circ} 40' 55''$ | -         | - | -    | - | 9.969218        |
| So is AC 1201.744                  | -         | - | -    | - | 3.079811        |
| To BC 1124.145                     | -         | - | -    | - | <u>3.050822</u> |

4. Wanting to know the distance between two inaccessible objects which lie in a direct line from the bottom of a tower of 120 feet in height, the angles of depression are measured, and found to be, of the nearest,  $57^{\circ}$ ; of the most remote,  $25^{\circ} 30'$ : required the distance between them.

*Ans.* 173.656 feet.

5. In order to find the distance between two trees, A and B, which could not be directly measured because of a pool which occupied the intermediate space, the distance of a third point C from each, was measured, viz. CA=588 feet and CB=672 feet, and also the contained angle ACB= $55^{\circ} 40'$ : required the distance AB.

*Ans.* 592.967 feet.

6. Being on a horizontal plane, and wanting to ascertain the height of a tower, standing on the top of an inaccessible hill, there were measured, the angle of elevation of the top of the hill  $40^{\circ}$ , and of the top of the tower  $51^{\circ}$ : then measuring in a direct line 180 feet farther from the hill, the angle of elevation of the top of the tower was  $33^{\circ} 45'$ : required the height of the tower.

*Ans.* 83.9983 feet.

7. Wanting to know the horizontal distance between two inaccessible objects A and B, and not finding any station from which both of them could be seen, two points C and D, were chosen, at a distance from each other equal to 200 yards, from the former of which A could be seen, and from the latter B, and at each of the points C and D a staff was set up. From C a distance CF was measured, not in the direction DC, equal to 200 yards, and from D, a distance DE equal to 200 yards, and the following angles were taken, viz. AFC= $83^{\circ}$  ACF= $54^{\circ} 31'$ , ACD= $53^{\circ} 30'$ , BDC= $156^{\circ} 25'$ , BDE= $54^{\circ} 30'$ , and BED= $88^{\circ} 30'$ : required the distance AB.

*Ans.* 345.46 yards.

8. From a station P there can be seen three objects, A, B and C, whose distances from each other are known, viz. AB=800, AC=600, and BC=400 yards. There are also measured the horizontal angles, APC= $33^{\circ} 45'$ , BPC= $22^{\circ} 30'$ . It is required, from these data, to determine the three distances PA, PC and PB.

*Ans.* PA=710.193, PC=1042.522, PB=934.291 yards.

## SPHERICAL TRIGONOMETRY.

I. It has already been shown that a spherical triangle is formed by the arcs of three great circles intersecting each other on the surface of a sphere, (Book IX. Def. 1). Hence, every spherical triangle has six parts: the sides and three angles.

*Spherical Trigonometry* explains the methods of determining, by calculation, the unknown sides and angles of a spherical triangle when any three of the six parts are given.

II. Any two parts of a spherical triangle are said to be of the *same species* when they are both less or both greater than  $90^\circ$ ; and they are of different species when one is less and the other greater than  $90^\circ$ .

III. Let ABC be a spherical triangle, and O the centre of the sphere. Let the sides of the triangle be designated by letters corresponding to their opposite angles: that is, the side opposite the angle A by  $a$ , the side opposite B by  $b$ , and the side opposite C by  $c$ . Then the angle COB will be represented by  $a$ , the angle COA by  $b$  and the angle BOA by  $c$ . The angles of the spherical triangle will be equal to the angles included between the planes which determine its sides (Book IX. Prop. VI.).

From any point A, of the edge OA, draw AD perpendicular to the plane COB. From D draw DH perpendicular to OB, and DK perpendicular to OC; and draw AH and AK: the last lines will be respectively perpendicular to OB and OC, (Book VI. Prop. VI.)

The angle DHA will be equal to the angle B of the spherical triangle, and the angle DKA to the angle C.

The two right angled triangles OKA, ADK, will give the proportions

$$R : \sin AOK :: OA : AK, \text{ or, } R \times AK = OA \sin b.$$

$$R : \sin AKD :: AK : AD, \text{ or, } R \times AD = AK \sin C.$$

Hence,  $R^2 \times AD = AO \sin b \sin C$ , by substituting for AK its value taken from the first equation.

In like manner the triangles AHO, ADH, right angled at H and D, give

$$R : \sin c :: AO : AH, \text{ or } R \times AH = AO \sin c$$

$$R : \sin B :: AH : AD, \text{ or } R \times AD = AH \sin B.$$

$$\text{Hence, } R^2 \times AD = AO \sin c \sin B.$$

Equating this with the value of  $R^2 \times AD$ , before found, and dividing by  $AO$ , we have

$$\sin b \sin C = \sin c \sin B, \text{ or } \frac{\sin C}{\sin B} = \frac{\sin c}{\sin b} \quad (1)$$

$$\text{or, } \sin B : \sin C :: \sin b : \sin c \text{ that is,}$$

*The sines of the angles of a spherical triangle are to each other as the sines of their opposite sides.*

IV. From K draw KE perpendicular to OB, and from D draw DF parallel to OB. Then will the angle  $DKF = COB = a$ , since each is the complement of the angle EKO.

In the right angled triangle OAH, we have

$$R : \cos c :: OA : OH; \text{ hence}$$

$$AO \cos c = R \times OH = R \times OE + R.DF.$$

In the right-angled triangle OKE

$$R : \cos a :: OK : OE, \text{ or } R \times OE = OK \cos a.$$

But in the right angled triangle OKA

$$R : \cos b :: OA : OK, \text{ or } R \times OK = OA \cos b.$$

$$\text{Hence } R \times OE = OA \cdot \frac{\cos a \cos b}{R}$$

In the right-angled triangle KFD

$$R : \sin a : KD : DF, \text{ or } R \times DF = KD \sin a.$$

But in the right angled triangles OAK, ADK, we have

$$R : \sin b :: OA : AK, \text{ or } R \times AK = OA \sin b$$

$$R : \cos K : AK : KD, \text{ or } R \times KD = AK \cos C$$

$$\text{hence } KD = \frac{OA \sin b \cos C}{R^2}, \text{ and}$$

$$R \times DF = \frac{OA \sin a \sin b \cos C}{R^2} : \text{ therefore}$$

$$OA \cos c = \frac{OA \cos a \cos b}{R} + \frac{AO \sin a \sin b \cos C}{R^2}, \text{ or}$$

$$R^2 \cos c = R \cos a \cos b + \sin a \sin b \cos C.$$

Similar equations may be deduced for each of the other sides. Hence, generally,

$$\left. \begin{aligned} R^2 \cos a &= R \cos b \cos c + \sin b \sin c \cos A. \\ R^2 \cos b &= R \cos a \cos c + \sin a \sin c \cos B. \\ R^2 \cos c &= R \cos b \cos a + \sin b \sin a \cos C. \end{aligned} \right\} \quad (2.)$$

That is, *radius square into the cosine of either side of a spherical triangle is equal to radius into the rectangle of the cosines of the two other sides plus the rectangle of the sines of those sides into the cosine of their included angle.*

V. Each of the formulas designated (2) involves the three sides of the triangle together with one of the angles. These formulas are used to determine the angles when the three sides are known. It is necessary, however, to put them under another form to adapt them to logarithmic computation.

Taking the first equation, we have

$$\cos A = \frac{R^2 \cos a - R \cos b \cos c}{\sin b \sin c}$$

Adding  $R$  to each member, we have

$$R + \cos A = \frac{R^2 \cos a + R \sin b \sin c - R \cos b \cos c}{\sin b \sin c}$$

$$\text{But, } R + \cos A = \frac{2 \cos \frac{1}{2} A}{R} \quad (\text{Art. XXIII.}), \text{ and}$$

$$R \sin b \sin c - R \cos b \cos c = -R^2 \cos (b+c) \quad (\text{Art. XIX.});$$

$$\text{hence, } \frac{2 \cos \frac{1}{2} A}{R} = \frac{R^2 (\cos a - \cos (b+c))}{\sin b \sin c} =$$

$$2 R \frac{\sin \frac{1}{2} (a+b+c) \sin \frac{1}{2} (b+c-a)}{\sin b \sin c} \quad (\text{Art. XXIII}).$$

Putting  $s = a + b + c$ , we shall have

$$\frac{1}{2}s = \frac{1}{2}(a+b+c) \text{ and } \frac{1}{2}s - a = \frac{1}{2}(b+c-a) : \text{ hence}$$

$$\left. \begin{aligned} \cos \frac{1}{2} A &= R \sqrt{\frac{\sin \frac{1}{2} (s) \sin (\frac{1}{2} s - a)}{\sin b \sin c}} \\ \cos \frac{1}{2} B &= R \sqrt{\frac{\sin \frac{1}{2} (s) \sin (\frac{1}{2} s - b)}{\sin a \sin c}} \\ \cos \frac{1}{2} C &= R \sqrt{\frac{\sin \frac{1}{2} (s) \sin (\frac{1}{2} s - c)}{\sin a \sin b}} \end{aligned} \right\} \quad (3.)$$

Had we subtracted each member of the first equation from  $R$ , instead of adding, we should, by making similar reductions, have found

$$\left. \begin{aligned} \sin \frac{1}{2} A &= R \sqrt{\frac{\sin \frac{1}{2}(a+b-c) \sin \frac{1}{2}(a+c-b)}{\sin b \sin c}} \\ \sin \frac{1}{2} B &= R \sqrt{\frac{\sin \frac{1}{2}(a+b-c) \sin \frac{1}{2}(b+c-a)}{\sin a \sin c}} \\ \sin \frac{1}{2} C &= R \sqrt{\frac{\sin \frac{1}{2}(a+c-b) \sin \frac{1}{2}(b+c-a)}{\sin a \sin b}} \end{aligned} \right\} (4.)$$

Putting  $s = a + b + c$ , we shall have

$\frac{1}{2}s - a = \frac{1}{2}(b + c - a)$ ,  $\frac{1}{2}s - b = \frac{1}{2}(a + c - b)$ , and  $\frac{1}{2}s - c = \frac{1}{2}(a + b - c)$   
hence,

$$\left. \begin{aligned} \sin \frac{1}{2} A &= R \sqrt{\frac{\sin (\frac{1}{2}s - c) \sin (\frac{1}{2}s - b)}{\sin b \sin c}} \\ \sin \frac{1}{2} B &= R \sqrt{\frac{\sin (\frac{1}{2}s - c) \sin (\frac{1}{2}s - a)}{\sin a \sin c}} \\ \sin \frac{1}{2} C &= R \sqrt{\frac{\sin (\frac{1}{2}s - b) \sin (\frac{1}{2}s - a)}{\sin a \sin b}} \end{aligned} \right\} (5.)$$

VI. We may deduce the value of the side of a triangle in terms of the three angles by applying equations (4.), to the polar triangle. Thus, if  $a', b', c'$ ;  $A', B', C'$ , represent the sides and angles of the polar triangle, we shall have

$$\begin{aligned} A &= 180^\circ - a', \quad B = 180^\circ - b', \quad C = 180^\circ - c'; \\ a &= 180^\circ - A', \quad b = 180^\circ - B', \quad \text{and} \quad c = 180^\circ - C' \end{aligned}$$

(Book IX. Prop. VII.): hence, omitting the ', since the equations are applicable to any triangle, we shall have

$$\left. \begin{aligned} \cos \frac{1}{2} a &= R \sqrt{\frac{\cos \frac{1}{2}(A+B-C) \cos \frac{1}{2}(A+C-B)}{\sin B \sin C}} \\ \cos \frac{1}{2} b &= R \sqrt{\frac{\cos \frac{1}{2}(A+B-C) \cos \frac{1}{2}(B+C-A)}{\sin A \sin C}} \\ \cos \frac{1}{2} c &= R \sqrt{\frac{\cos \frac{1}{2}(A+C-B) \cos \frac{1}{2}(B+C-A)}{\sin A \sin B}} \end{aligned} \right\} (6.)$$

Putting  $S=A+B+C$ , we shall have

$$\begin{aligned}\frac{1}{2}S-A &= \frac{1}{2}(C+B-A), \quad \frac{1}{2}S-B = \frac{1}{2}(A+C-B) \text{ and} \\ \frac{1}{2}S-C &= \frac{1}{2}(A+B-C), \text{ hence}\end{aligned}$$

$$\left. \begin{aligned}\cos \frac{1}{2}a &= R \sqrt{\frac{\cos (\frac{1}{2}S-C) \cos (\frac{1}{2}S-B)}{\sin B \sin C}} \\ \cos \frac{1}{2}b &= R \sqrt{\frac{\cos (\frac{1}{2}S-C) \cos (\frac{1}{2}S-A)}{\sin A \sin C}} \\ \cos \frac{1}{2}c &= R \sqrt{\frac{\cos (\frac{1}{2}S-B) \cos (\frac{1}{2}S-A)}{\sin A \sin B}}\end{aligned}\right\} (7.)$$

VII. If we apply equations (2.) to the polar triangle, we shall have

$$-R^2 \cos A' = R \cos B' \cos C' - \sin B' \sin C' \cos a'.$$

Or, omitting the ', since the equation is applicable to any triangle, we have the three symmetrical equations,

$$\left. \begin{aligned}R^2 \cos A &= \sin B \sin C \cos a - R \cos B \cos C \\ R^2 \cos B &= \sin A \sin C \cos b - R \cos A \cos C \\ R^2 \cos C &= \sin A \sin B \cos c - R \cos A \cos B\end{aligned}\right\} (8.)$$

That is, *radius square into the cosine of either angle of a spherical triangle, is equal to the rectangle of the sines of the two other angles into the cosine of their included side, minus radius into the rectangle of their cosines.*

VIII. All the formulas necessary for the solution of spherical triangles, may be deduced from equations marked (2.). If we substitute for  $\cos b$  in the third equation, its value taken from the second, and substitute for  $\cos^2 a$  its value  $R^2 - \sin^2 a$ , and then divide by the common factor  $R \sin a$ , we shall have

$$R \cos c \sin a = \sin c \cos a \cos B + R \sin b \cos C.$$

$$\text{But equation (1.) gives } \sin b = \frac{\sin B \sin c}{\sin C};$$

hence, by substitution,

$$R \cos c \sin a = \sin c \cos a \cos B + R \frac{\sin B \cos C \sin c}{\sin C}$$

Dividing by  $\sin c$ , we have

$$R \frac{\cos c}{\sin c} \sin a = \cos a \cos B + R \frac{\sin B \cos C}{\sin C}.$$

$$\text{But, } \frac{\cos}{\sin} = \frac{\cot}{R} \quad (\text{Art. XVII.}).$$

Therefore,  $\cot c \sin a = \cos a \cos B + \cot C \sin B$ .

Hence, we may write the three symmetrical equations,

$$\left. \begin{aligned} \cot a \sin b &= \cos b \cos C + \cot A \sin C \\ \cot b \sin c &= \cos c \cos A + \cot B \sin A \\ \cot c \sin a &= \cos a \cos B + \cot C \sin B \end{aligned} \right\} (9.)$$

That is, in every spherical triangle, the cotangent of one of the sides into the sine of a second side, is equal to the cosine of the second side into the cosine of the included angle, plus the cotangent of the angle opposite the first side into the sine of the included angle.

IX. We shall terminate these formulas by demonstrating *Napier's Analogies*, which serve to simplify several cases in the solution of spherical triangles.

If from the first and third of equations (2.),  $\cos c$  be eliminated, there will result, after a little reduction,

$$R \cos A \sin c = R \cos a \sin b - \cos C \sin a \cos b.$$

By a simple permutation, this gives

$$R \cos B \sin c = R \cos b \sin a - \cos C \sin b \cos a.$$

Hence by adding these two equations, and reducing, we shall have

$$\sin c (\cos A + \cos B) = (R - \cos C) \sin (a + b)$$

But since  $\frac{\sin c}{\sin C} = \frac{\sin a}{\sin A} = \frac{\sin b}{\sin B}$ , we shall have

$$\sin c (\sin A + \sin B) = \sin C (\sin a + \sin b), \quad \text{and}$$

$$\sin c (\sin A - \sin B) = \sin C (\sin a - \sin b).$$

Dividing these two equations successively by the preceding one; we shall have

$$\begin{aligned} \frac{\sin A + \sin B}{\cos A + \cos B} &= \frac{\sin C}{R - \cos C} \cdot \frac{\sin a + \sin b}{\sin (a + b)} \\ \frac{\sin A - \sin B}{\cos A + \cos B} &= \frac{\sin C}{R - \cos C} \cdot \frac{\sin a - \sin b}{\sin (a + b)}. \end{aligned}$$

R

And reducing these by the formulas in Articles XXIII. and XXIV., the e will result

$$\text{tang } \frac{1}{2}(A+B) = \cot \frac{1}{2}C \cdot \frac{\cos \frac{1}{2}(a-b)}{\cos \frac{1}{2}(a+b)}$$

$$\text{tang } \frac{1}{2}(A-B) = \cot \frac{1}{2}C \cdot \frac{\sin \frac{1}{2}(a-b)}{\sin \frac{1}{2}(a+b)}.$$

Hence, two sides  $a$  and  $b$  with the included angle  $C$  being given, the two other angles  $A$  and  $B$  may be found by the analogies,

$$\cos \frac{1}{2}(a+b) : \cos \frac{1}{2}(a-b) :: \cot \frac{1}{2}C : \text{tang } \frac{1}{2}(A+B)$$

$$\sin \frac{1}{2}(a+b) : \sin \frac{1}{2}(a-b) :: \cot \frac{1}{2}C : \text{tang } \frac{1}{2}(A-B).$$

If these same analogies are applied to the polar triangle of  $ABC$ , we shall have to put  $180^\circ - A'$ ,  $180^\circ - B'$ ,  $180^\circ - a'$ ,  $180^\circ - b'$ ,  $180^\circ - c'$ , instead of  $a, b, A, B, C$ , respectively; and for the result, we shall have after omitting the ', these two analogies,

$$\cos \frac{1}{2}(A+B) : \cos \frac{1}{2}(A-B) :: \text{tang } \frac{1}{2}c : \text{tang } \frac{1}{2}(a+b)$$

$$\sin \frac{1}{2}(A+B) : \sin \frac{1}{2}(A-B) :: \text{tang } \frac{1}{2}c : \text{tang } \frac{1}{2}(a-b)$$

by means of which, when a side  $c$  and the two adjacent angles  $A$  and  $B$  are given, we are enabled to find the two other sides  $a$  and  $b$ . These four proportions are known by the name of *Napier's Analogies*.

X. In the case in which there are given two sides and an angle opposite one of them, there will in general be two solutions corresponding to the two results in Case II. of rectilineal triangles. It is also plain that this ambiguity will extend itself to the corresponding case of the polar triangle, that is, to the case in which there are given two angles and a side opposite one of them. In every case we shall avoid all false solutions by recollecting,

1st. *That every angle, and every side of a spherical triangle is less than  $180^\circ$ .*

2d. *That the greater angle lies opposite the greater side, and the least angle opposite the least side, and reciprocally.*

#### NAPIER'S CIRCULAR PARTS.

XI. Besides the analogies of Napier already demonstrated, that Geometer also invented rules for the solution of all the cases of right angled spherical triangles.

In every right angled spherical triangle BAC, there are six parts: three sides and three angles. If we omit the consideration of the right angle, which is always known, there will be five remaining parts, two of which must be given before the others can be determined.

The *circular parts*, as they are called, are the two sides  $c$  and  $b$ , about the right angle, the complements of the oblique angles  $B$  and  $C$ , and the complement of the hypotenuse  $a$ . Hence there are five circular parts. The right angle  $A$  not being a circular part, is supposed not to separate the circular parts  $c$  and  $b$ , so that these parts are considered as adjacent to each other.

If any two parts of the triangle be given, their corresponding circular parts will also be known, and these together with a required part, will make three parts under consideration. Now, these three parts *will all lie together, or one of them will be separated from both of the others*. For example, if  $B$  and  $c$  were given, and  $a$  required, the three parts considered would lie together. But if  $B$  and  $C$  were given, and  $b$  required, the parts would not lie together; for,  $B$  would be separated from  $C$  by the part  $a$ , and from  $b$  by the part  $c$ . In either case  $B$  is the *middle part*. Hence, when there are three of the circular parts under consideration, *the middle part is that one of them to which both of the others are adjacent, or from which both of them are separated*. In the former case the parts are said to be *adjacent*, and in the latter case the parts are said to be *opposite*.

This being premised, we are now to prove the following rules for the solution of right angled spherical triangles, which it must be remembered apply to the *circular parts*, as already defined.

1st. *Radius into the sine of the middle part is equal to the rectangle of the tangents of the adjacent parts.*

2d. *Radius into the sine of the middle part is equal to the rectangle of the cosines of the opposite parts.*

These rules are proved by assuming each of the five circular parts, in succession, as the middle part, and by taking the extremes first opposite, then adjacent. Having thus fixed the three parts which are to be considered, take that one of the general equations for oblique angled triangles, which shall contain the three corresponding parts of the triangle, together with the right angle: then make  $A = 90^\circ$ , and after making the reductions corresponding to this supposition, the resulting equation will prove the rule for that particular case.

For example, let comp.  $a$  be the middle part and the extremes opposite. The equation to be applied in this case must contain  $a, b, c$ , and  $A$ . The first of equations (2.) contains these four quantities: hence

$$R^2 \cos a = R \cos b \cos c + \sin b \sin c \cos A.$$

If  $A=90^\circ$   $\cos A=0$ ; hence

$$R \cos a = \cos b \cos c;$$

that is, radius into the sine of the middle part, (which is the complement of  $a$ ), is equal to the rectangle of the cosines of the opposite parts.

Suppose now that the complement of  $a$  were the middle part and the extremes adjacent. The equation to be applied must contain the four quantities  $a, B, C$ , and  $A$ . It is the first of equations (8.).

$$R^2 \cos A = \sin B \sin C \cos a - R \cos B \cos C.$$

Making  $A=90^\circ$ , we have

$$\sin B \sin C \cos a = R \cos B \cos C, \quad \text{or}$$

$$R \cos a = \cot B \cot C;$$

that is, radius into the sine of the middle part is equal to the rectangle of the tangent of the complement of  $B$  into the tangent of the complement of  $C$ , that is, to the rectangle of the tangents of the adjacent *circular parts*.

Let us now take the comp.  $B$ , for the middle part and the extremes opposite. The two other parts under consideration will then be the perpendicular  $b$  and the angle  $C$ . The equation to be applied must contain the four parts  $A, B, C$ , and  $b$ : it is the second of equations (8.),

$$R^2 \cos B = \sin A \sin C \cos b - R \cos A \cos C.$$

Making  $A=90^\circ$ , we have, after dividing by  $R$ ,

$$R \cos B = \sin C \cos b.$$

Let comp.  $B$  be still the middle part and the extremes adjacent. The equation to be applied must then contain the four parts  $a, B, c$ , and  $A$ . It is similar to equations (9.).

$$\cot a \sin c = \cos c \cos B + \cot A \sin B$$

But if  $A=90^\circ$ ,  $\cot A=0$ ; hence,

$$\cot a \sin c = \cos c \cos B; \quad \text{or}$$

$$R \cos B = \cot a \tan c.$$

And by pursuing the same method of demonstration when each circular part is made the middle part, we obtain the five following equations, which embrace all the cases.

$$\left. \begin{aligned} R \cos a &= \cos b \cos c = \cot B \cot C \\ R \cos B &= \cos b \sin C = \cot a \tan c \\ R \cos C &= \cos c \sin B = \cot a \tan b \\ R \sin b &= \sin a \sin B = \tan c \cot C \\ R \sin c &= \sin a \sin C = \tan b \cot B \end{aligned} \right\} (10.)$$

We see from these equations that, *if the middle part is required we must begin the proportion with radius ; and when one of the extremes is required we must begin the proportion with the other extreme.*

We also conclude, from the first of the equations, that when the hypotenuse is less than  $90^\circ$ , the sides  $b$  and  $c$  will be of the same species, and also that the angles  $B$  and  $C$  will likewise be of the same species. When  $a$  is greater than  $90^\circ$ , the sides  $b$  and  $c$  will be of different species, and the same will be true of the angles  $B$  and  $C$ . We also see from the two last equations that a side and its opposite angle will always be of the same species.

These properties are proved by considering the algebraic signs which have been attributed to the trigonometrical lines, and by remembering that the two members of an equation must always have the same algebraic sign.

#### SOLUTION OF RIGHT ANGLED SPHERICAL TRIANGLES BY LOGARITHMS.

It is to be observed, that when any element is discovered in the form of its sine only, there may be two values for this element, and consequently two triangles that will satisfy the question ; because, the same sine which corresponds to an angle or an arc, corresponds likewise to its supplement. This will not take place, when the unknown quantity is determined by means of its cosine, its tangent, or cotangent. In all these cases, the sign will enable us to decide whether the element in question is less or greater than  $90^\circ$  ; the element will be less than  $90^\circ$ , if its cosine, tangent, or cotangent, has the sign  $+$  ; it will be greater if one of these quantities has the sign  $-$ .

In order to discover the species of the required element of the triangle, we shall annex the minus sign to the logarithms of all the elements whose cosines, tangents, or cotangents, are negative. Then by recollecting that the product of the two

extremes has the same sign as that of the means, we can at once determine the sign which is to be given to the required element, and then its species will be known.

## EXAMPLES.

1. In the right angled spherical triangle BAC, right angled at A, there are given  $a=64^\circ 40'$  and  $b=42^\circ 12'$ : required the remaining parts.

First, to find the side  $c$ .

The hypotenuse  $a$  corresponds to the middle part, and the extremes are opposite: hence

$$R \cos a = \cos b \cos c, \text{ or}$$

|           |     |                     |           |      |                 |
|-----------|-----|---------------------|-----------|------|-----------------|
| As cos    | $b$ | $42^\circ 12'$      | ar.-comp. | log. | 0.130296        |
| Is to     | $R$ | -                   | -         | -    | 10.000000       |
| So is cos | $a$ | $64^\circ 40'$      | -         | -    | 9.631326        |
| To cos    | $c$ | $54^\circ 43' 07''$ | -         | -    | <u>9.761622</u> |

To find the angle  $B$ .

The side  $b$  will be the middle part and the extremes opposite: hence

$$R \sin b = \cos (\text{comp. } a) \times \cos (\text{comp. } B) = \sin a \sin B.$$

|           |     |                     |           |      |                 |
|-----------|-----|---------------------|-----------|------|-----------------|
| As sin    | $a$ | $64^\circ 40'$      | ar.-comp. | log. | 0.043911        |
| Is to sin | $b$ | $42^\circ 12'$      | -         | -    | 9.827189        |
| So is     | $R$ | -                   | -         | -    | 10.000000       |
| To sin    | $B$ | $48^\circ 00' 14''$ | -         | -    | <u>9.871100</u> |

To find the angle  $C$ .

The angle  $C$  is the middle part and the extremes adjacent; hence

$$R \cos C = \cot a \tan b.$$

|            |     |                     |           |      |                 |
|------------|-----|---------------------|-----------|------|-----------------|
| As         | $R$ | -                   | ar.-comp. | log. | 0.000000        |
| Is to cot  | $a$ | $64^\circ 40'$      | -         | -    | 9.675237        |
| So is tang | $b$ | $42^\circ 12'$      | -         | -    | 9.957485        |
| To cos     | $C$ | $64^\circ 34' 46''$ | -         | -    | <u>9.632722</u> |

2. In a right angled triangle BAC, there are given the hypotenuse  $a=105^\circ 34'$ , and the angle  $B=80^\circ 40'$ : required the remaining parts.

To find the angle C.

The hypotenuse will be the middle part and the extremes adjacent: hence,

$$R \cos a = \cot B \cot C.$$

|           |   |              |           |      |                   |
|-----------|---|--------------|-----------|------|-------------------|
| As cot    | B | 80° 40'      | ar.-comp. | log. | 0.784220 +        |
| Is to cos | a | 105° 34'     | -         | -    | 9.428717—         |
| So is     | R | -            | -         | -    | 10.000000 +       |
| To cot    | C | 148° 30' 54" | -         | -    | <u>10.212937—</u> |

Since the cotangent of C is negative the angle C is greater than 90°, and is the supplement of the arc which would correspond to the cotangent, if it were positive.

To find the side c.

The angle B will correspond to the middle part, and the extremes will be adjacent: hence,

$$R \cos B = \cot a \tan c.$$

|           |   |              |           |      |                  |
|-----------|---|--------------|-----------|------|------------------|
| As cot    | a | 105° 34'     | ar.-comp. | log. | 0.555053—        |
| Is to     | R | -            | -         | -    | 10.000000 +      |
| So is cos | B | 80° 40'      | -         | -    | 9.209992 +       |
| To tang   | c | 149° 47' 36" | -         | -    | <u>9.765045—</u> |

To find the side b.

The side b will be the middle part and the extremes opposite: hence,

$$R \sin b = \sin a \sin B.$$

|           |   |             |           |      |   |                 |
|-----------|---|-------------|-----------|------|---|-----------------|
| As        | R | -           | ar. comp. | log. | - | 0.000000        |
| To sin    | a | 105° 34'    | -         | -    | - | 9.983770        |
| So is sin | B | 80° 40'     | -         | -    | - | 9.994212        |
| To sin    | b | 71° 54' 33" | -         | -    | - | <u>9.977982</u> |

#### OF QUADRANTAL TRIANGLES.

A *quadrantal* spherical triangle is one which has one of its sides equal to 90°.

Let BAC be a quadrantal triangle in which the side  $a = 90^\circ$ . If we pass to the corresponding polar triangle, we shall have  $A' = 180^\circ - a = 90^\circ$ ,  $B' = 180^\circ - b$ ,  $C' = 180^\circ - c$ ,  $a' = 180^\circ - A$ ,  $b' = 180^\circ - B$ ,  $c' = 180^\circ - C$ ; from which we see, that the polar triangle will be

right angled at  $A'$ , and hence every case may be referred to a right angled triangle.

But we can solve the quadrantal triangle by means of the right angled triangle in a manner still more simple.

In the quadrantal triangle  $BAC$ , in which  $BC=90^\circ$ , produce the side  $CA$  till  $CD$  is equal to  $90^\circ$ , and conceive the arc of a great circle to be drawn through  $B$  and  $D$ . Then  $C$  will be the pole of the arc  $BD$ , and the angle  $C$  will be measured by  $BD$  (Book IX. Prop. VI.), and the angles  $CBD$  and  $D$  will be right angles. Now before the remaining parts of the quadrantal triangle can

be found, at least two parts must be given in addition to the side  $BC=90^\circ$ ; in which case two parts of the right angled triangle  $BDA$ , together with the right angle, become known. Hence the conditions which enable us to determine one of these triangles, will enable us also to determine the other.

3. In the quadrantal triangle  $BCA$ , there are given  $CB=90^\circ$ , the angle  $C=42^\circ 12'$ , and the angle  $A=115^\circ 20'$ : required the remaining parts.

Having produced  $CA$  to  $D$ , making  $CD=90^\circ$  and drawn the arc  $BD$ , there will then be given in the right angled triangle  $BAD$ , the side  $a=C=42^\circ 12'$ , and the angle  $BAD=180^\circ - BAC=180^\circ - 115^\circ 20' = 64^\circ 40'$ , to find the remaining parts.

To find the side  $d$ .

The side  $a$  will be the middle part, and the extremes opposite: hence,

$$R \sin a = \sin A \sin d.$$

|           |     |                     |           |      |                 |
|-----------|-----|---------------------|-----------|------|-----------------|
| As sin    | A   | $64^\circ 40'$      | ar.-comp. | log. | 0.043911        |
| Is to     | R   | -                   | -         | -    | 10.000000       |
| So is sin | $a$ | $42^\circ 12'$      | -         | -    | 9.827189        |
| To sin    | $d$ | $48^\circ 00' 14''$ | -         | -    | <u>9.871100</u> |

To find the angle  $B$ .

The angle  $A$  will correspond to the middle part, and the extremes will be opposite: hence

$$R \cos A = \sin B \cos a.$$

|           |     |                     |           |      |                 |
|-----------|-----|---------------------|-----------|------|-----------------|
| As cos    | $a$ | $42^\circ 12'$      | ar.-comp. | log. | 0.130296        |
| Is to     | R   | -                   | -         | -    | 10.000000       |
| So is cos | A   | $64^\circ 40'$      | -         | -    | 9.631326        |
| To sin    | B   | $35^\circ 16' 53''$ | -         | -    | <u>9.761622</u> |

To find the side  $b$ .

The side  $b$  will be the middle part, and the extremes adjacent: hence,

$$R \sin b = \cot A \tan a.$$

|                |              |   |           |      |                 |
|----------------|--------------|---|-----------|------|-----------------|
| As             | R            | - | ar.-comp. | log. | 0.000000        |
| Is to cot A    | 64° 40'      | - | -         | -    | 9.675237        |
| So is tang $a$ | 42° 12'      | - | -         | -    | 9.957485        |
| To sin $b$     | 25° 25' 14'' | - | -         | -    | <u>9.632722</u> |

$$\begin{aligned} \text{Hence, } CA &= 90^\circ - b = 90^\circ - 25^\circ 25' 14'' = 64^\circ 34' 46'' \\ CBA &= 90^\circ - ABD = 90^\circ - 35^\circ 16' 53'' = 54^\circ 43' 07'' \\ BA &= d \quad \quad \quad = 48^\circ 00' 15''. \end{aligned}$$

4. In the right angled triangle BAC, right angled at A, there are given  $a = 115^\circ 25'$ , and  $c = 60^\circ 59'$ : required the remaining parts.

$$\text{Ans. } \begin{cases} B = 148^\circ 56' 45'' \\ C = 75^\circ 30' 33'' \\ b = 152^\circ 13' 50''. \end{cases}$$

5. In the right angled spherical triangle BAC, right angled at A, there are given  $c = 116^\circ 30' 43''$ , and  $b = 29^\circ 41' 32''$ : required the remaining parts.

$$\text{Ans. } \begin{cases} C = 103^\circ 52' 46'' \\ B = 32^\circ 30' 22'' \\ a = 112^\circ 48' 58''. \end{cases}$$

6. In a quadrantal triangle, there are given the quadrantal side  $= 90^\circ$ , an adjacent side  $= 115^\circ 09'$ , and the included angle  $= 115^\circ 55'$ : required the remaining parts.

$$\text{Ans. } \begin{cases} \text{side, } & 113^\circ 18' 19'' \\ \text{angles, } & \begin{cases} 117^\circ 33' 52'' \\ 101^\circ 40' 07''. \end{cases} \end{cases}$$

#### SOLUTION OF OBLIQUE ANGLED TRIANGLES BY LOGARITHMS.

There are six cases which occur in the solution of oblique angled spherical triangles.

1. Having given two sides, and an angle opposite one of them.

2. Having given two angles, and a side opposite one of them.

3. Having given the three sides of a triangle, to find the angles.

4. Having given the three angles of a triangle, to find the sides.
5. Having given two sides and the included angle.
6. Having given two angles and the included side.

## CASE I.

*Given two sides, and an angle opposite one of them, to find the remaining parts.*

For this case we employ equation (1.) ;

$$\text{As } \sin a : \sin b :: \sin A : \sin B.$$

*Ex. 1.* Given the side  $a=44^\circ 13' 45''$ ,  $b=84^\circ 14' 29''$  and the angle  $A=32^\circ 26' 07''$  : required the remaining parts.

To find the angle B.

|           |     |  |           |      |                 |
|-----------|-----|--|-----------|------|-----------------|
| As sin    | $a$ | $44^\circ 13' 45''$                                | ar.-comp. | log. | 0.156437        |
| Is to sin | $b$ | $84^\circ 14' 29''$                                | -         | -    | 9.997803        |
| So is sin | $A$ | $32^\circ 26' 07''$                                | -         | -    | 9.729445        |
| To sin    | $B$ | $49^\circ 54' 38''$ or $\sin B' 130^\circ 5' 22''$ |           |      | <u>9.883685</u> |

Since the sine of an arc is the same as the sine of its supplement, there will be two angles corresponding to the logarithmic sine 9.883685 and these angles will be supplements of each other. It does not follow however that both of them will satisfy all the other conditions of the question. If they do, there will be two triangles  $ACB'$ ,  $ACB$  ; if not, there will be but one.

To determine the circumstances under which this ambiguity arises, we will consider the 2d of equations (2.).

$$R^2 \cos b = R \cos a \cos c + \sin a \sin c \cos B.$$

from which we obtain

$$\cos B = \frac{R^2 \cos b - R \cos a \cos c}{\sin a \sin c}.$$

Now if  $\cos b$  be greater than  $\cos a$ , we shall have

$$R^2 \cos b > R \cos a \cos c,$$

or the sign of the second member of the equation will depend on that of  $\cos b$ . Hence  $\cos B$  and  $\cos b$  will have the same

sign, or  $B$  and  $b$  will be of the same species, and there will be but one triangle.

But when  $\cos b > \cos a$ ,  $\sin b < \sin a$  : hence,

*If the sine of the side opposite the required angle be less than the sine of the other given side, there will be but one triangle.*

If however,  $\sin b > \sin a$ , the  $\cos b$  will be less than  $\cos a$ , and it is plain that such a value may then be given to  $c$  as to render

$$R^2 \cos b < R \cos a \cos c,$$

or the sign of the second member may be made to depend on  $\cos c$ .

We can therefore give such values to  $c$  as to satisfy the two equations

$$\begin{aligned} +\cos B &= \frac{R^2 \cos b - R \cos a \cos c}{\sin a \sin c} \\ -\cos B &= \frac{R^2 \cos b - R \cos a \cos c}{\sin a \sin c}. \end{aligned}$$

Hence, *if the sine of the side opposite the required angle be greater than the sine of the other given side, there will be two triangles which will fulfil the given conditions.*

Let us, however, consider the triangle  $ACB$ , in which we are yet to find the base  $AB$  and the angle  $C$ . We can find these parts most readily by dividing the triangle into two right angled triangles. Draw the arc  $CD$  perpendicular to the base  $AB$  : then in each of the triangles there will be given the hypotenuse and the angle at the base. And generally, when it is proposed to solve an oblique angled triangle by means of the right angled triangle, we must so draw the perpendicular that *it shall pass through the extremity of a given side, and lie opposite to a given angle.*

To find the angle  $C$ , in the triangle  $ACD$ .

|           |     |             |           |      |                 |
|-----------|-----|-------------|-----------|------|-----------------|
| As cot    | A   | 32° 26' 07" | ar.-comp. | log. | 9.803105        |
| Is to     | R   | -           | -         | -    | 10.000000       |
| So is cos | b   | 84° 14' 29" | -         | -    | 9.001465        |
| To cot    | ACD | 86° 21' 06" | -         | -    | <u>8.804570</u> |

To find the angle  $C$  in the triangle  $DCB$ .

|           |     |             |           |      |                 |
|-----------|-----|-------------|-----------|------|-----------------|
| As cot    | B   | 49° 54' 38" | ar.-comp. | log. | 0.074810        |
| Is to     | R   | -           | -         | -    | 10.000000       |
| So is cos | a   | 44° 13' 45" | -         | -    | 9.855250        |
| To cot    | DCB | 49° 35' 38" | -         | -    | <u>9.930060</u> |

Hence  $ACB = 135^\circ 56' 47''$ .

To find the side AB.

|           |   |              |           |      |                 |
|-----------|---|--------------|-----------|------|-----------------|
| As sin    | A | 32° 26' 07"  | ar.-comp. | log. | 0.270555        |
| Is to sin | C | 135° 56' 47" | -         | -    | 9.842191        |
| So is sin | a | 44° 13' 45"  | -         | -    | 9.843563        |
| To sin    | c | 115° 16' 29" | -         | -    | <u>9.956309</u> |

The arc  $64^\circ 43' 31''$ , which corresponds to  $\sin c$  is not the value of the side AB : for the side AB must be greater than  $b$ , since it lies opposite to a greater angle. But  $b=84^\circ 14' 29''$  : hence the side AB must be the supplement of  $64^\circ 43' 31''$ , or  $115^\circ 16' 29''$ .

*Ex. 2.* Given  $b=91^\circ 03' 25''$ ,  $a=40^\circ 36' 37''$ , and  $A=35^\circ 57' 15''$  : required the remaining parts, when the obtuse angle B is taken.

$$\text{Ans. } \begin{cases} B=115^\circ 35' 41'' \\ C=58^\circ 30' 57'' \\ c=70^\circ 58' 52'' \end{cases}$$

#### CASE II.

*Having given two angles and a side opposite one of them, to find the remaining parts.*

For this case, we employ the equation (1.)

$$\sin A : \sin B :: \sin a : \sin b.$$

*Ex. 1.* In a spherical triangle ABC, there are given the angle  $A=50^\circ 12'$ ,  $B=58^\circ 8'$ , and the side  $a=62^\circ 42'$  ; to find the remaining parts.

To find the side  $b$ .

|           |   |                                |           |      |                 |
|-----------|---|--------------------------------|-----------|------|-----------------|
| As sin    | A | 50° 12'                        | ar.-comp. | log. | 0.114478        |
| Is to sin | B | 58° 08'                        | -         | -    | 9.929050        |
| So is sin | a | 62° 42'                        | -         | -    | 9.948715        |
| To sin    | b | 79° 12' 10'', or 100° 47' 50'' |           |      | <u>9.992243</u> |

We see here, as in the last example, that there are two arcs corresponding to the 4th term of the proportion, and these arcs are supplements of each other, since they have the same sine. It does not follow, however, that both of them will satisfy all the conditions of the question. If they do, there will be two triangles ; if not, there will be but one.

To determine when there are two triangles, and also when there is but one, let us consider the second of equations (8.)

$R^2 \cos B = \sin A \sin C \cos b - R \cos A \cos C$ , which gives

$$\cos b = \frac{R^2 \cos B + R \cos A \cos C}{\sin A \sin C}.$$

Now, if  $\cos B$  be greater than  $\cos A$  we shall have

$$R^2 \cos B > R \cos A \cos C,$$

and hence the sign of the second member of the equation will depend on that of  $\cos B$ , and consequently  $\cos b$  and  $\cos B$  will have the same algebraic sign, or  $b$  and  $B$  will be of the same species. But when  $\cos B > \cos A$  the  $\sin B < \sin A$ : hence

*If the sine of the angle opposite the required side be less than the sine of the other given angle, there will be but one solution.*

If, however,  $\sin B > \sin A$ , the  $\cos B$  will be less than  $\cos A$ , and it is plain that such a value may then be given to  $\cos C$ , as to render

$$R^2 \cos B < R \cos A \cos C,$$

or the sign of the second member of the equation may be made to depend on  $\cos C$ . We can therefore give such values to  $C$  as to satisfy the two equations

$$\begin{aligned} +\cos b &= \frac{R^2 \cos B + R \cos A \cos C}{\sin A \sin C}, \quad \text{and} \\ -\cos b &= \frac{R^2 \cos B + R \cos A \cos C}{\sin A \sin C}. \end{aligned}$$

Hence, *if the sine of the angle opposite the required side be greater than the sine of the other given angle there will be two solutions.*

Let us first suppose the side  $b$  to be less than  $90^\circ$ , or equal to  $79^\circ 12' 10''$ .

If now, we let fall from the angle  $C$  a perpendicular on the base  $BA$ , the triangle will be divided into two right angled triangles, in each of which there will be two parts known besides the right angle.

Calculating the parts by Napier's rules we find,

$$C = 130^\circ 54' 28''$$

$$c = 119^\circ 03' 26''.$$

If we take the side  $b = 100^\circ 47' 50''$ , we shall find

$$C = 156^\circ 15' 06''$$

$$c = 152^\circ 14' 18''.$$

*Ex. 2.* In a spherical triangle ABC there are given  $A=103^{\circ} 59' 57''$ ,  $B=46^{\circ} 18' 7''$ , and  $a=42^{\circ} 8' 48''$ ; required the remaining parts.

There will but one triangle, since  $\sin B < \sin A$ .

$$\text{Ans. } \begin{cases} b = 30^{\circ} \\ C = 36^{\circ} 7' 54'' \\ c = 24^{\circ} 3' 56'' \end{cases}$$

### CASE III.

*Having given the three sides of a spherical triangle to find the angles.*

For this case we use equations (3.).

$$\cos \frac{1}{2} A = R \sqrt{\frac{\sin \frac{1}{2} s \sin (\frac{1}{2} s - a)}{\sin b \sin c}}$$

*Ex. 1.* In an oblique angled spherical triangle there are given  $a=56^{\circ} 40'$ ,  $b=83^{\circ} 13'$  and  $c=114^{\circ} 30'$ ; required the angles.

|   |                        |           |                  |
|---|------------------------|-----------|------------------|
| $\frac{1}{2}(a+b+c)=\frac{1}{2}s = 127^{\circ} 11' 30''$  |                        |           |                  |
| $\frac{1}{2}(b+c-a)=(\frac{1}{2}s-a)=70^{\circ} 31' 30''$ |                        |           |                  |
| Log sin $\frac{1}{2}s$                                    | $127^{\circ} 11' 30''$ | - - -     | 9.901250         |
| log sin $(\frac{1}{2}s-a)$                                | $70^{\circ} 31' 30''$  | - - -     | 9.974413         |
| —log sin $b$  | $83^{\circ} 13'$       | ar.-comp. | 0.003051         |
| —log sin $c$  | $114^{\circ} 30'$      | ar.-comp. | 0.040977         |
| Sum   | - - -                  | - - -     | <u>19.919691</u> |
| Half sum = log cos $\frac{1}{2}A$                         | $24^{\circ} 15', 39''$ | - -       | <u>9.959845</u>  |

Hence, angle  $A=48^{\circ} 31' 18''$ .

The addition of twice the logarithm of radius, or 20, to the numerator of the quantity under the radical just cancels the 20 which is to be subtracted on account of the arithmetical complements, to that the 20, in both cases, may be omitted.

Applying the same formulas to the angles B and C, we find,

$$B = 62^{\circ} 55' 46''$$

$$C = 125^{\circ} 19' 02''.$$

*Ex. 2.* In a spherical triangle there are given  $a=40^{\circ} 18' 29''$ ,  $b=67^{\circ} 14' 28''$ , and  $c=89^{\circ} 47' 6''$ ; required the three angles.

$$\text{Ans. } \begin{cases} A = 34^{\circ} 22' 16'' \\ B = 53^{\circ} 35' 16'' \\ C = 119^{\circ} 13' 32'' \end{cases}$$

CASE IV.

*Having given the three angles of a spherical triangle, to find the three sides.*

For this case we employ equations (7.)

$$\cos \frac{1}{2}a = R \sqrt{\frac{\cos(\frac{1}{2}S-B)\cos(\frac{1}{2}S-C)}{\sin B \sin C}}.$$

*Ex. 1.* In a spherical triangle ABC there are given  $A=48^{\circ} 30'$ ,  $B=125^{\circ} 20'$ , and  $C=62^{\circ} 54'$ ; required the sides.

|                            |                           |                        |           |
|----------------------------|---------------------------|------------------------|-----------|
| $\frac{1}{2}(A+B+C)$       | $=\frac{1}{2}S$           | $= 118^{\circ} 22'$    |           |
| $(\frac{1}{2}S-A)$         | -                         | $= 69^{\circ} 52'$     |           |
| $(\frac{1}{2}S-B)$         | -                         | $= 6^{\circ} 58'$      |           |
| $(\frac{1}{2}S-C)$         | -                         | $= 55^{\circ} 28'$     |           |
| Log cos $(\frac{1}{2}S-B)$ | $-6^{\circ} 58'$          | -                      | 9.996782  |
| log cos $(\frac{1}{2}S-C)$ | $55^{\circ} 28'$          | -                      | 9.753495  |
| —log sin B                 | $125^{\circ} 20'$         | ar.-comp.              | 0.088415  |
| —log sin C                 | $62^{\circ} 54'$          | ar.-comp.              | 0.050506  |
| Sum                        | -                         | -                      | 19.889198 |
| Half sum                   | $=\log \cos \frac{1}{2}A$ | $=28^{\circ} 19' 48''$ | 9.944599  |

Hence, side  $a=56^{\circ} 39' 36''$ .

In a similar manner we find,

$$\begin{aligned} b &= 114^{\circ} 29' 58'' \\ c &= 83^{\circ} 12' 06''. \end{aligned}$$

*Ex. 2.* In a spherical triangle ABC, there are given  $A=109^{\circ} 55' 42''$ ,  $B=116^{\circ} 38' 33''$ , and  $C=120^{\circ} 43' 37''$ ; required the three sides.

$$\text{Ans. } \begin{cases} a = 98^{\circ} 21' 40'' \\ b = 109^{\circ} 50' 22'' \\ c = 115^{\circ} 13' 26'' \end{cases}$$

CASE V.

*Having given in a spherical triangle, two sides and their included angle, to find the remaining parts.*

For this case we employ the two first of Napier's Analogies.

$$\cos \frac{1}{2}(a+b) : \cos \frac{1}{2}(a-b) :: \cot \frac{1}{2}C : \tan \frac{1}{2}(A+B)$$

$$\sin \frac{1}{2}(a+b) : \sin \frac{1}{2}(a-b) :: \cot \frac{1}{2}C : \tan \frac{1}{2}(A-B).$$

Having found the half sum and the half difference of the angles A and B, the angles themselves become known; for, the greater angle is equal to the half sum plus the half difference, and the lesser is equal to the half sum minus the half difference.

The greater angle is then to be placed opposite the greater side. The remaining side of the triangle can then be found by Case II.

*Ex. 1.* In a spherical triangle ABC, there are given  $a=68^{\circ} 46' 2''$ ,  $b=37^{\circ} 10'$ , and  $C=39^{\circ} 23'$ ; to find the remaining parts

$$\frac{1}{2}(a+b)=52^{\circ} 58' 1'', \frac{1}{2}(a-b)=15^{\circ} 48' 1'', \frac{1}{2}C=19^{\circ} 41' 30''.$$

|           |                    |                       |      |           |                  |
|-----------|--------------------|-----------------------|------|-----------|------------------|
| As cos    | $\frac{1}{2}(a+b)$ | $52^{\circ} 58' 1''$  | log. | ar.-comp. | 0.220210         |
| Is to cos | $\frac{1}{2}(a-b)$ | $15^{\circ} 48' 1''$  | -    | -         | 9.983271         |
| So is cot | $\frac{1}{2}C$     | $19^{\circ} 41' 30''$ | -    | -         | 10.446254        |
| Totang    | $\frac{1}{2}(A+B)$ | $77^{\circ} 22' 25''$ | -    | -         | <u>10.649735</u> |

|           |                    |                       |      |           |                 |
|-----------|--------------------|-----------------------|------|-----------|-----------------|
| As sin    | $\frac{1}{2}(a+b)$ | $52^{\circ} 58' 1''$  | log. | ar.-comp. | 0.097840        |
| Is to sin | $\frac{1}{2}(a-b)$ | $15^{\circ} 48' 1''$  | -    | -         | 9.435016        |
| So is cot | $\frac{1}{2}C$     | $19^{\circ} 41' 30''$ | -    | -         | 10.446254       |
| Totang    | $\frac{1}{2}(A-B)$ | $43^{\circ} 37' 21''$ | -    | -         | <u>9.979110</u> |

$$\text{Hence, } A=77^{\circ} 22' 25'' + 43^{\circ} 37' 21'' = 120^{\circ} 59' 46''$$

$$B=77^{\circ} 22' 25'' - 43^{\circ} 37' 21'' = 33^{\circ} 45' 04''$$

$$\text{side } c \quad - \quad - \quad - \quad = 43^{\circ} 37' 37''.$$

*Ex. 2.* In a spherical triangle ABC, there are given  $b=83^{\circ} 19' 42''$ ,  $c=23^{\circ} 27' 46''$ , the contained angle  $A=20^{\circ} 39' 48''$ ; to find the remaining parts.

$$\text{Ans. } \begin{cases} B=156^{\circ} 30' 16'' \\ C=9^{\circ} 11' 48'' \\ a=61^{\circ} 32' 12''. \end{cases}$$

#### CASE VI.

*In a spherical triangle, having given two angles and the included side to find the remaining parts.*

For this case we employ the second of Napier's Analogies.

$$\cos \frac{1}{2}(A+B) : \cos \frac{1}{2}(A-B) :: \tan \frac{1}{2}c : \tan \frac{1}{2}(a+b)$$

$$\sin \frac{1}{2}(A+B) : \sin \frac{1}{2}(A-B) :: \tan \frac{1}{2}c : \tan \frac{1}{2}(a-b).$$

From which  $a$  and  $b$  are found as in the last case. The remaining angle can then be found by Case I.

*Ex. 1.* In a spherical triangle ABC, there are given  $A=81^{\circ} 38' 20''$ ,  $B=70^{\circ} 9' 38''$ ,  $c=59^{\circ} 16' 23''$ ; to find the remaining parts.

$$\frac{1}{2}(A+B)=75^{\circ} 53' 59'', \frac{1}{2}(A-B)=5^{\circ} 44' 21'', \frac{1}{2}c=29^{\circ} 38' 11''.$$

$$\text{As } \cos \frac{1}{2}(A+B) \quad 75^{\circ} 53' 59'' \quad \log. \quad \text{ar.-comp.} \quad 0.613287$$

$$\text{To } \cos \frac{1}{2}(A-B) \quad 5^{\circ} 44' 21'' \quad - \quad - \quad 9.997818$$

$$\text{So is } \tan \frac{1}{2}c \quad 29^{\circ} 38' 11'' \quad - \quad - \quad 9.755051$$

$$\text{To } \tan \frac{1}{2}(a+b) \quad 66^{\circ} 42' 52'' \quad - \quad - \quad \underline{10.366156}$$

$$\text{As } \sin \frac{1}{2}(A+B) \quad 75^{\circ} 53' 59'' \quad \log. \quad \text{ar.-comp.} \quad 0.013286$$

$$\text{To } \sin \frac{1}{2}(A-B) \quad 5^{\circ} 14' 21'' \quad - \quad - \quad 9.000000$$

$$\text{So is } \tan \frac{1}{2}c \quad 29^{\circ} 38' 11'' \quad - \quad - \quad 9.755051$$

$$\text{To } \tan \frac{1}{2}(a-b) \quad 3^{\circ} 21' 25'' \quad - \quad - \quad \underline{8.768337}$$

$$\text{Hence } a=66^{\circ} 42' 52'' + 3^{\circ} 21' 25'' = 70^{\circ} 04' 17''$$

$$b=66^{\circ} 42' 52'' - 3^{\circ} 21' 25'' = 63^{\circ} 21' 27''$$

$$\text{angle } C \quad - \quad - \quad = 64^{\circ} 46' 33''.$$

*Ex. 2.* In a spherical triangle ABC, there are given  $A=34^{\circ} 15' 3''$ ,  $B=42^{\circ} 15' 13''$ , and  $c=76^{\circ} 35' 36''$ ; to find the remaining parts.

$$\text{Ans. } \begin{cases} a=40^{\circ} 0' 10'' \\ b=50^{\circ} 10' 30'' \\ C=58^{\circ} 23' 41''. \end{cases}$$

## MENSURATION OF SURFACES.

The area, or content of a surface, is determined by finding how many times it contains some other surface which is assumed as the unit of measure. Thus, when we say that a square yard contains 9 square feet, we should understand that one square foot is taken for the unit of measure, and that this unit is contained 9 times in the square yard.

The most convenient unit of measure for a surface, is a square whose side is the linear unit in which the linear dimensions of the figure are estimated. Thus, if the linear dimensions are feet, it will be most convenient to express the area in square feet; if the linear dimensions are yards, it will be most convenient to express the area in square yards, &c.

We have already seen (Book IV. Prop. IV. Sch.), that the term, rectangle or product of two lines, designates the rectangle constructed on the lines as sides; and that the numerical value of this product expresses the number of times which the rectangle contains its unit of measure.

### PROBLEM I.

To find the area of a square, a rectangle, or a parallelogram.

**RULE.**—*Multiply the base by the altitude, and the product will be the area* (Book IV. Prop. V.).

1. To find the area of a parallelogram, the base being 12.25 and the altitude 8.5. *Ans.* 104.125.

2. What is the area of a square whose side is 204.3 feet? *Ans.* 41738.49 sq. ft.

3. What is the content, in square yards, of a rectangle whose base is 66.3 feet, and altitude 33.3 feet? *Ans.* 245.31.

4. To find the area of a rectangular board, whose length is  $12\frac{1}{2}$  feet, and breadth 9 inches. *Ans.*  $9\frac{3}{8}$  sq. ft.

5. To find the number of square yards of painting in a parallelogram, whose base is 37 feet, and altitude 5 feet 3 inches. *Ans.*  $21\frac{7}{2}$ .

### PROBLEM II.

To find the area of a triangle.

#### CASE I.

When the base and altitude are given.

**RULE.**—*Multiply the base by the altitude, and take half the product. Or, multiply one of these dimensions by half the other* (Book IV. Prop. VI.).

1. To find the area of a triangle, whose base is 625 and altitude 520 feet. Ans. 162500 sq. ft.

2. To find the number of square yards in a triangle, whose base is 40 and altitude 30 feet. Ans.  $66\frac{2}{3}$ .

3. To find the number of square yards in a triangle, whose base is 49 and altitude  $25\frac{1}{4}$  feet. Ans. 68.7361.

### CASE II.

When two sides and their included angle are given.

**RULE.**—Add together the logarithms of the two sides and the logarithmic sine of their included angle; from this sum subtract the logarithm of the radius, which is 10, and the remainder will be the logarithm of double the area of the triangle. Find, from the table, the number answering to this logarithm, and divide it by 2; the quotient will be the required area.

Let BAC be a triangle, in which there are given BA, BC, and the included angle B.

From the vertex A draw AD, perpendicular to the base BC, and represent the area of the triangle by Q. Then,

$$R : \sin B :: BA : AD \text{ (Trig. Th. I.) :}$$

hence, 
$$AD = \frac{BA \times \sin B}{R}$$

But, 
$$Q = \frac{BC \times AD}{2} \text{ (Book IV. Prop. VI.) ;}$$

hence, by substituting for AD its value, we have

$$Q = \frac{BC \times BA \times \sin B}{2R}, \text{ or } 2Q = \frac{BC \times BA \times \sin B}{R}.$$

Taking the logarithms of both numbers, we have

$\log. 2Q = \log. BC + \log. BA + \log. \sin B - \log. R$ ;  
which proves the rule as enunciated.

1. What is the area of a triangle whose sides are,  $BC = 125.81$ ,  $BA = 57.65$ , and the included angle  $B = 57^\circ 25'$ ?

$$\text{Then, } \log. 2Q = \begin{cases} +\log. BC & 125.81 & \dots & 2.099715 \\ +\log. BA & 57.65 & \dots & 1.760799 \\ +\log. \sin B & 57^\circ 25' & \dots & 9.925626 \\ -\log. R & & & -10. \end{cases}$$

$$\log. 2Q \dots \dots \dots 3.786140$$

and  $2Q = 6111.4$ , or  $Q = 3055.7$ , the required area.

2. What is the area of a triangle whose sides are 33 and 40 and their included angle  $28^\circ 57'$ ? *Ans.* 290.427.

3. What is the number of square yards in a triangle of which the sides are 25 feet and 21.25 feet, and their included angle  $45^\circ$ ? *Ans.* 20.8694.

## CASE III.

When the three sides are known.

**RULE.**—1. Add the three sides together, and take half their sum.

2. From this half-sum subtract each side separately.

3. Multiply together the half-sum and each of the three remainders, and the product will be the square of the area of the triangle. Then, extract the square root of this product, for the required area.

Or, After having obtained the three remainders, add together the logarithm of the half-sum and the logarithms of the respective remainders, and divide their sum by 2: the quotient will be the logarithm of the area.

Let ABC be the given triangle. Take CD equal to the side CB, and draw DB; draw AE parallel to DB, meeting CB produced, in E: then CE will be equal to CA. Draw CFG perpendicular to AE and DB, and it will bisect them at the points G and F. Draw FHI parallel to AB, meeting CA in H, and EA produced, in I. Lastly, with the centre H and radius HF, describe the circumference of a circle, meeting CA produced in K: this circumference will pass through I, because  $AI = FB = FD$ , therefore,  $HF = HI$ ; and it will also pass through the point G, because FGI is a right angle.

Now, since  $HA = HD$ , CH is equal to half the sum of the sides CA, CB; that is,  $CH = \frac{1}{2}CA + \frac{1}{2}CB$ ; and since HK is equal to  $\frac{1}{2}IF = \frac{1}{2}AB$ , it follows that

$$CK = \frac{1}{2}AC + \frac{1}{2}CB + \frac{1}{2}AB = \frac{1}{2}S,$$

by representing the sum of the sides by S.

Again,  $HK = HI = \frac{1}{2}IF = \frac{1}{2}AB$ , or  $KL = AB$ .

Hence,  $CL = CK - KL = \frac{1}{2}S - AB$ ,

and  $AK = CK - CA = \frac{1}{2}S - CA$ ,

and  $AL = DK = CK - CD = \frac{1}{2}S - CB$ .

Now,  $AG \times CG =$  the area of the triangle ACE,  
and  $AG \times FG =$  the area of the triangle ABE;  
therefore,  $AG \times CF =$  the area of the triangle ACB

Also, by similar triangles,

$$AG : CG :: DF : CF, \text{ or } AI : CF;$$

therefore,  $AG \times CF = \text{triangle } ACB = CG \times DF = CG \times AI$ ;  
consequently,  $AG \times CF \times CG \times AI = \text{square of the area } ACB$ .

But  $CG \times CF = CK \times CL = \frac{1}{2}S(\frac{1}{2}S - AB)$ ,  
and  $AG \times AI = AK \times AL = (\frac{1}{2}S - CA) \times (\frac{1}{2}S - CB)$ ;  
therefore,  $AG \times CF \times CG \times AI = \frac{1}{2}S(\frac{1}{2}S - AB) \times (\frac{1}{2}S - CA) \times (\frac{1}{2}S - CB)$ , which is equal to the square of the area of the triangle ACB.

1. To find the area of a triangle whose three sides are 20, 30, and 40.

|              |             |            |              |
|--------------|-------------|------------|--------------|
| 20           | 45          | 45         | 45 half-sum. |
| 30           | 20          | 30         | 40           |
| 40           | —           | —          | —            |
| —            | 25 1st rem. | 15 2d rem. | 5 3d rem     |
| 2)90         |             |            |              |
| —            |             |            |              |
| 45 half-sum. |             |            |              |

Then,  $45 \times 25 \times 15 \times 5 = 84375$ .

The square root of which is 290.4737, the required area.

2. How many square yards of plastering are there in a triangle whose sides are 30, 40, and 50 feet? *Ans.*  $66\frac{2}{3}$ .

### PROBLEM III.

To find the area of a trapezoid.

**RULE.**—*Add together the two parallel sides: then multiply their sum by the altitude of the trapezoid, and half the product will be the required area (Book IV. Prop. VII.).*

1. In a trapezoid the parallel sides are 750 and 1225, and the perpendicular distance between them is 1540; what is the area? *Ans.* 152075.

2. How many square feet are contained in a plank, whose length is 12 feet 6 inches, the breadth at the greater end 15 inches, and at the less end 11 inches? *Ans.*  $13\frac{3}{4}$  sq. ft.

3. How many square yards are there in a trapezoid, whose parallel sides are 240 feet, 320 feet, and altitude 66 feet? *Ans.*  $2053\frac{1}{3}$ .

### PROBLEM IV.

To find the area of a quadrilateral.

**RULE.**—*Join two of the angles by a diagonal, dividing the quadrilateral into two triangles. Then, from each of the other angles let fall a perpendicular on the diagonal: then multiply*

*the diagonal by half the sum of the two perpendiculars, and the product will be the area.*

1. What is the area of the quadrilateral ABCD, the diagonal AC being 42, and the perpendiculars Dg, Bb, equal to 18 and 16 feet?

*Ans.* 714.

2. How many square yards of paving are there in the quadrilateral whose diagonal is 65 feet, and the two perpendiculars let fall on it 28 and  $33\frac{1}{2}$  feet?

*Ans.*  $222\frac{1}{2}$ .

#### PROBLEM V.

To find the area of an irregular polygon.

**RULE.**—*Draw diagonals dividing the proposed polygon into trapezoids and triangles. Then find the areas of these figures separately, and add them together for the content of the whole polygon.*

1. Let it be required to determine the content of the polygon ABCDE, having five sides.

Let us suppose that we have measured the diagonals and perpendiculars, and found  $AC=36.21$ ,  $EC=39.11$ ,  $Bb=4$ ,  $Dd=7.26$ ,  $Aa=4.18$ , required the area.

*Ans.* 296.1292.

#### PROBLEM VI.

To find the area of a long and irregular figure, bounded on one side by a right line.

**RULE.**—1. *At the extremities of the right line measure the perpendicular breadths of the figure, and do the same at several intermediate points, at equal distances from each other.*

2. *Add together the intermediate breadths and half the sum of the extreme ones: then multiply this sum by one of the equal parts of the base line: the product will be the required area, very nearly.*

Let AEea be an irregular figure, having for its base the right line AE. At the points A, B, C, D, and E, equally distant from each other, erect the perpendiculars Aa, Bb, Cc, Dd, Ee, to the

base line AE, and designate them respectively by the letters  $a, b, c, d$ , and  $e$ .

Then, the area of the trapezoid ABba =  $\frac{a+b}{2} \times AB$ ,

the area of the trapezoid BCcb =  $\frac{b+c}{2} \times BC$ ,

the area of the trapezoid CDdc =  $\frac{c+d}{2} \times CD$ ,

and the area of the trapezoid DEed =  $\frac{d+e}{2} \times DE$ ;

nence, their sum, or the area of the whole figure, is equal to

$$\left( \frac{a+b}{2} + \frac{b+c}{2} + \frac{c+d}{2} + \frac{d+e}{2} \right) \times AB,$$

since AB, BC, &c. are equal to each other. But this sum is also equal to

$$\left( \frac{a}{2} + b + c + d + \frac{e}{2} \right) \times AB,$$

which corresponds with the enunciation of the rule.

1. The breadths of an irregular figure at five equidistant places being 8.2, 7.4, 9.2, 10.2, and 8.6, and the length of the base 40, required the area.

|                           |                            |
|---------------------------|----------------------------|
| 8.2                       | 4)40                       |
| 8.6                       | —                          |
| —                         | 10 one of the equal parts. |
| 2(16.8                    | —                          |
| —                         |                            |
| 8.4 mean of the extremes. |                            |
| 7.4                       | 35.2 sum.                  |
| 9.2                       | 10                         |
| 10.2                      | —                          |
| —                         | 352 = area.                |
| 35.2 sum.                 | —                          |
| —                         |                            |

2. The length of an irregular figure being 84, and the breadths at six equidistant places 17.4, 20.6, 14.2, 16.5, 20.1, and 24.4; what is the area? Ans. 1550.64.

#### PROBLEM VII.

To find the area of a regular polygon.

**RULE I.**—Multiply half the perimeter of the polygon by the apothem, or perpendicular let fall from the centre on one of the sides, and the product will be the area required (Book V Prop. IX.).

**REMARK I.**—The following is the manner of determining the perpendicular when only one side and the number of sides of the regular polygon are known:—

First, divide 360 degrees by the number of sides of the polygon, and the quotient will be the angle at the centre; that is, the angle subtended by one of the equal sides. Divide this angle by 2, and half the angle at the centre will then be known.

Now, the line drawn from the centre to an angle of the polygon, the perpendicular let fall on one of the equal sides, and half this side, form a right-angled triangle, in which there are known, the base, which is half the equal side of the polygon, and the angle at the vertex. Hence, the perpendicular can be determined.

1. To find the area of a regular hexagon, whose sides are 20 feet each.

$$\begin{array}{r} 6)360^\circ \\ \hline \end{array}$$

$$60^\circ = ACB, \text{ the angle at the centre.}$$

$$30^\circ = ACD, \text{ half the angle at the centre}$$

Also,  $CAD = 90^\circ - ACD = 60^\circ$ ; and  $AD = 10$ .

|  |          |
|--|----------|
| Then, as $\sin ACD$ . . . $30^\circ$ , ar. comp. . . . . | 0.301030 |
| : $\sin CAD$ . . . $60^\circ$ . . . . .                  | 9.937531 |
| $\therefore AD$ . . . . . 10 . . . . .                   | 1.000000 |
| : $CD$ . . . 17.3205 . . . . .                           | 1.238561 |

Perimeter = 120, and half the perimeter = 60.

Then,  $60 \times 17.3205 = 1039.23$ , the area.

2. What is the area of an octagon whose side is 20?

*Ans.* 1931.36886.

**REMARK II.**—The area of a regular polygon of any number of sides is easily calculated by the above rule. Let the areas of the regular polygons whose sides are unity, or 1, be calculated and arranged in the following

TABLE.

| Names.            | Sides.     | Areas.     |
|-------------------|------------|------------|
| Triangle . . . .  | 3 . . . .  | 0.4330127  |
| Square . . . .    | 4 . . . .  | 1.0000000  |
| Pentagon . . . .  | 5 . . . .  | 1.7204774  |
| Hexagon . . . .   | 6 . . . .  | 2.5980762  |
| Heptagon . . . .  | 7 . . . .  | 3.6339124  |
| Octagon . . . .   | 8 . . . .  | 4.8284271  |
| Nonagon . . . .   | 9 . . . .  | 6.1818242  |
| Decagon . . . .   | 10 . . . . | 7.6942088  |
| Undecagon . . . . | 11 . . . . | 9.3656399  |
| Dodecagon . . . . | 12 . . . . | 11.1961524 |

Now, since the areas of similar polygons are to each other as the squares of their homologous sides (Book IV. Prop. XXVII.), we shall have

$$1^2 : \text{tabular area} :: \text{any side squared} : \text{area.}$$

Or, to find the area of any regular polygon, we have

RULE II.—1. *Square the side of the polygon.*

2. *Then multiply that square by the tabular area set opposite the polygon of the same number of sides, and the product will be the required area.*

1. What is the area of a regular hexagon whose side is 20?

$$20^2 = 400, \quad \text{tabular area} = 2.5980762.$$

Hence,  $2.5980762 \times 400 = 1039.2304800$ , as before.

2. To find the area of a pentagon whose side is 25.

$$\text{Ans. } 1075.298375.$$

3. To find the area of a decagon whose side is 20.

$$\text{Ans. } 3077.68352.$$

#### PROBLEM VIII.

To find the circumference of a circle when the diameter is given, or the diameter when the circumference is given.

RULE.—*Multiply the diameter by 3.1416, and the product will be the circumference; or, divide the circumference by 3.1416, and the quotient will be the diameter.*

It is shown (Book V. Prop. XIV.), that the circumference of a circle whose diameter is 1, is 3.1415926, or 3.1416. But since the circumferences of circles are to each other as their radii or diameters, we have, by calling the diameter of the second circle  $d$ ,

$$1 : d :: 3.1416 : \text{circumference,}$$

$$\text{or,} \quad d \times 3.1416 = \text{circumference.}$$

$$\text{Hence, also.} \quad d = \frac{\text{circumference}}{3.1416}$$

1. What is the circumference of a circle whose diameter is 25 ? *Ans.* 78.54.

2. If the diameter of the earth is 7921 miles, what is the circumference ? *Ans.* 24884.6136.

3. What is the diameter of a circle whose circumference is 11652.1904 ? *Ans.* 37.09.

4. What is the diameter of a circle whose circumference is 6850 ? *Ans.* 2180.41.

#### PROBLEM IX

To find the length of an arc of a circle containing any number of degrees.

**RULE.**—*Multiply the number of degrees in the given arc by 0.0087266, and the product by the diameter of the circle.*

Since the circumference of a circle whose diameter is 1, is 3.1416, it follows, that if 3.1416 be divided by 360 degrees, the quotient will be the length of an arc of 1 degree: that is,  

$$\frac{3.1416}{360} = 0.0087266 = \text{arc of one degree to the diameter 1.}$$

This being multiplied by the number of degrees in an arc, the product will be the length of that arc in the circle whose diameter is 1; and this product being then multiplied by the diameter, will give the length of the arc for any diameter whatever.

**REMARK.**—When the arc contains degrees and minutes, reduce the minutes to the decimal of a degree, which is done by dividing them by 60.

1. To find the length of an arc of 30 degrees, the diameter being 18 feet. *Ans.* 4.712364.

2. To find the length of an arc of  $12^{\circ} 10'$ , or  $12\frac{1}{6}^{\circ}$ , the diameter being 20 feet. *Ans.* 2.123472.

3. What is the length of an arc of  $10^{\circ} 15'$ , or  $10\frac{1}{4}^{\circ}$ , in a circle whose diameter is 68 ? *Ans.* 6.082396.

#### PROBLEM X.

To find the area of a circle.

**RULE I.**—*Multiply the circumference by half the radius (Book V. Prop. XII.).*

**RULE II.**—*Multiply the square of the radius by 3.1416 (Book V. Prop. XII. Cor. 2).*

1. To find the area of a circle whose diameter is 10 and circumference 31.416. *Ans.* 78.54.

2. Find the area of a circle whose diameter is 7 and circumference 21.9912. Ans. 38.4846.

3. How many square yards in a circle whose diameter is  $3\frac{1}{2}$  feet? Ans. 1.069016.

4. What is the area of a circle whose circumference is 12 feet? Ans. 11.4595.

PROBLEM XI.

To find the area of the sector of a circle.

RULE I.—*Multiply the arc of the sector by half the radius (Book V. Prop. XII. Cor. 1).*

RULE II.—*Compute the area of the whole circle: then say, as 360 degrees is to the degrees in the arc of the sector, so is the area of the whole circle to the area of the sector.*

1. To find the area of a circular sector whose arc contains 18 degrees, the diameter of the circle being 3 feet. Ans. 0.35343.

2. To find the area of a sector whose arc is 20 feet, the radius being 10. Ans. 100.

3. Required the area of a sector whose arc is  $147^\circ 29'$ , and radius 25 feet. Ans. 804.3986.

PROBLEM XII.

To find the area of a segment of a circle.

RULE.—1. *Find the area of the sector having the same arc, by the last problem.*

2. *Find the area of the triangle formed by the chord of the segment and the two radii of the sector.*

3. *Then add these two together for the answer when the segment is greater than a semicircle, and subtract them when it is less.*

1. To find the area of the segment ACB, its chord AB being 12, and the radius EA, 10 feet.

|           |                      |       |                |
|-----------|----------------------|-------|----------------|
| As EA     | 10 ar. comp.         | . . . | 9.000000       |
| : AD      | 6 . . . . .          |       | 0.778151       |
| :: sin D  | $90^\circ$ . . . . . |       | 10.000000      |
|           |                      |       |                |
| : sin AED | $36^\circ 52'$       | =     | 36.87 9.778151 |
|           |                      |       | 2              |

73.74 = the degrees in the arc ACB

Then,  $0.0087266 \times 73.74 \times 20 = 12.87 = \text{arc ACB, nearly}$   
 $\quad\quad\quad 5$

---

$$64.35 = \text{area EACB.}$$

---

Again,  $\sqrt{EA^2 - AD^2} = \sqrt{100 - 36} = \sqrt{64} = 8 = ED$ ;  
 and  $6 \times 8 = 48 = \text{the area of the triangle EAB.}$

Hence, sect. EACB—EAB =  $64.35 - 48 = 16.35 = \text{ACB.}$

2. Find the area of the segment whose height is 18, the diameter of the circle being 50. Ans. 636.4834.

3. Required the area of the segment whose chord is 16, the diameter being 20. Ans. 44.764.

### PROBLEM XIII.

To find the area of a circular ring: that is, the area included between the circumferences of two circles which have a common centre.

**RULE.**—Take the difference between the areas of the two circles. Or, subtract the square of the less radius from the square of the greater, and multiply the remainder by 3.1416.

For the area of the larger is . . . . .  $R^2\pi$   
 and of the smaller . . . . .  $r^2\pi$

---

Their difference, or the area of the ring, is  $(R^2 - r^2)\pi$ .

1. The diameters of two concentric circles being 10 and 6, required the area of the ring contained between their circumferences. Ans. 50.2656.

2. What is the area of the ring when the diameters of the circles are 10 and 20? Ans. 235.62.

### PROBLEM XIV.

To find the area of an ellipse, or oval.\*

**RULE.**—Multiply the two semi-axes together, and their product by 3.1416.

1. Required the area of an ellipse whose semi-axes AE, EC, are 35 and 25.  
Ans. 2748.9.

\* Although this rule, and the one for the following problem, cannot be demonstrated without the aid of principles not yet considered, still it was thought best to insert them, as they complete the rules necessary for the mensuration of planes.

2. Required the area of an ellipse whose axes are 24 and 18.  
*Ans.* 339.2928.

PROBLEM XV.

To find the area of any portion of a parabola.

**RULE.**—*Multiply the base by the perpendicular height, and take two-thirds of the product for the required area.*

1. To find the area of the parabola ACB, the base AB being 20 and the altitude CD, 18.

*Ans.* 240.

- 2 Required the area of a parabola, the base being 20 and the altitude 30.  
*Ans.* 400.

MENSURATION OF SOLIDS.

The mensuration of solids is divided into two parts.

1st. The mensuration of their surfaces ; and,

2dly. The mensuration of their solidities.

We have already seen, that the unit of measure for plane surfaces is a square whose side is the unit of length.

A curved line which is expressed by numbers is also referred to a unit of length, and its numerical value is the number of times which the line contains its unit. If, then, we suppose the linear unit to be reduced to a right line, and a square constructed on this line, this square will be the unit of measure for curved surfaces.

The unit of solidity is a cube, the face of which is equal to the superficial unit in which the surface of the solid is estimated, and the edge is equal to the linear unit in which the linear dimensions of the solid are expressed (Book VII. Prop. XIII. Sch.).

The following is a table of solid measures :—

|                    |              |   |                |
|--------------------|--------------|---|----------------|
| 1728               | cubic inches | = | 1 cubic foot.  |
| 27                 | cubic feet   | = | 1 cubic yard.  |
| 4492 $\frac{1}{8}$ | cubic feet   | = | 1 cubic rod.   |
| 282                | cubic inches | = | 1 ale gallon.  |
| 231                | cubic inches | = | 1 wine gallon. |
| 2150.42            | cubic inches | = | 1 bushel.      |

## OF POLYEDRONS, OR SURFACES BOUNDED BY PLANES.

## PROBLEM I.

To find the surface of a right prism.

**RULE.**—*Multiply the perimeter of the base by the altitude, and the product will be the convex surface (Book VII. Prop. I.). To this add the area of the two bases, when the entire surface is required.*

1. To find the surface of a cube, the length of each side being 20 feet. *Ans.* 2400 sq. ft.

2. To find the whole surface of a triangular prism, whose base is an equilateral triangle, having each of its sides equal to 18 inches, and altitude 20 feet. *Ans.* 91.949.

3. What must be paid for lining a rectangular cistern with lead at 2*d.* a pound, the thickness of the lead being such as to require 7*lbs.* for each square foot of surface; the inner dimensions of the cistern being as follows, viz. the length 3 feet 2 inches, the breadth 2 feet 8 inches, and the depth 2 feet 6 inches? *Ans.* 2*l.* 3*s.* 10 $\frac{5}{9}$ *d.*

## PROBLEM II.

To find the surface of a regular pyramid.

**RULE.**—*Multiply the perimeter of the base by half the slant height, and the product will be the convex surface (Book VII. Prop. IV.): to this add the area of the base, when the entire surface is required.*

1. To find the convex surface of a regular triangular pyramid, the slant height being 20 feet, and each side of the base 3 feet. *Ans.* 90 sq. ft.

2. What is the entire surface of a regular pyramid, whose slant height is 15 feet, and the base a pentagon, of which each side is 25 feet? *Ans.* 2012.798.

## PROBLEM III.

To find the convex surface of the frustum of a regular pyramid.

**RULE.**—*Multiply the half-sum of the perimeters of the two bases by the slant height of the frustum, and the product will be the convex surface (Book VII. Prop. IV. Cor.).*

1. How many square feet are there in the convex surface of the frustum of a square pyramid, whose slant height is 10 feet, each side of the lower base 3 feet 4 inches, and each side of the upper base 2 feet 2 inches? *Ans.* 110 sq. ft.

2. What is the convex surface of the frustum of an heptagonal pyramid whose slant height is 55 feet, each side of the lower base 8 feet, and each side of the upper base 4 feet? *Ans.* 2310 sq. ft.

## PROBLEM IV

To find the solidity of a prism.

**RULE.**—1. *Find the area of the base.*

2. *Multiply the area of the base by the altitude, and the product will be the solidity of the prism (Book VII. Prop. XIV.).*

1. What is the solid content of a cube whose side is 24 inches? *Ans.* 13824.

2. How many cubic feet in a block of marble, of which the length is 3 feet 2 inches, breadth 2 feet 8 inches, and height or thickness 2 feet 6 inches? *Ans.*  $21\frac{1}{9}$ .

3. How many gallons of water, ale measure, will a cistern contain, whose dimensions are the same as in the last example? *Ans.*  $129\frac{17}{47}$ .

4. Required the solidity of a triangular prism, whose height is 10 feet, and the three sides of its triangular base 3, 4, and 5 feet. *Ans.* 60.

## PROBLEM V.

To find the solidity of a pyramid.

**RULE.**—*Multiply the area of the base by one-third of the altitude, and the product will be the solidity (Book VII. Prop. XVII.).*

1. Required the solidity of a square pyramid, each side of its base being 30, and the altitude 25. *Ans.* 7500.

2. To find the solidity of a triangular pyramid, whose altitude is 30, and each side of the base 3 feet. *Ans.* 38.9711.

3. To find the solidity of a triangular pyramid, its altitude being 14 feet 6 inches, and the three sides of its base 5, 6, and 7 feet. *Ans.* 71.0352.

4. What is the solidity of a pentagonal pyramid, its altitude being 12 feet, and each side of its base 2 feet? *Ans.* 27.5276.

5. What is the solidity of an hexagonal pyramid, whose altitude is 6.4 feet, and each side of its base 6 inches? *Ans.* 1.38564.

## PROBLEM VI.

To find the solidity of the frustum of a pyramid.

**RULE.**—*Add together the areas of the two bases of the frustum and a mean proportional between them, and then multiply the sum by one-third of the altitude (Book VII. Prop. XVIII.).*

1. To find the number of solid feet in a piece of timber, whose bases are squares, each side of the lower base being 15 inches, and each side of the upper base 6 inches, the altitude being 24 feet.

*Ans.* 19.5.

2. Required the solidity of a pentagonal frustum, whose altitude is 5 feet, each side of the lower base 18 inches, and each side of the upper base 6 inches.

*Ans.* 9.31925.

## Definitions.

1. A *wedge* is a solid bounded by five planes: viz. a rectangle ABCD, called the base of the wedge; two trapezoids ABHG, DCHG, which are called the sides of the wedge, and which intersect each other in the edge GH; and the two triangles GDA, HCB, which are called the ends of the wedge.

When AB, the length of the base, is equal to GH, the trapezoids ABHG, DCHG, become parallelograms, and the wedge is then one-half the parallelepipedon described on the base ABCD, and having the same altitude with the wedge.

The altitude of the wedge is the perpendicular let fall from any point of the line GH, on the base ABCD.

2. A *rectangular prismoid* is a solid resembling the frustum of a quadrangular pyramid. The upper and lower bases are rectangles, having their corresponding sides parallel, and the convex surface is made up of four trapezoids. The altitude of the prismoid is the perpendicular distance between its bases.

## PROBLEM VII.

To find the solidity of a wedge.

**RULE.**—*To twice the length of the base add the length of the edge. Multiply this sum by the breadth of the base, and then by the altitude of the wedge, and take one-sixth of the product for the solidity.*

Let  $L=AB$ , the length of the base.

$l=GH$ , the length of the edge.

$b=BC$ , the breadth of the base.

$h=PG$ , the altitude of the wedge.

Then,  $L-l=AB-GH=AM$ .

Suppose  $AB$ , the length of the base, to be equal to  $GH$ , the length of the edge, the solidity will then be equal to half the parallelipedon having the same base and the same altitude (Book VII. Prop. VII.). Hence, the solidity will be equal to  $\frac{1}{2}bhl$  (Book VII. Prop. XIV.).

If the length of the base is greater than that of the edge, let a section  $MNG$  be made parallel to the end  $BCH$ . The wedge will then be divided into the triangular prism  $BCH-M$ , and the quadrangular pyramid  $G-AMND$ .

The solidity of the prism  $=\frac{1}{2}bhl$ , the solidity of the pyramid  $=\frac{1}{3}bh(L-l)$ ; and their sum,  $\frac{1}{2}bhl + \frac{1}{3}bh(L-l) = \frac{1}{6}bh3l + \frac{1}{6}bh2L - \frac{1}{6}bh2l = \frac{1}{6}bh(2L+l)$ .

If the length of the base is less than the length of the edge, the solidity of the wedge will be equal to the difference between the prism and pyramid, and we shall have for the solidity of the wedge,

$$\frac{1}{2}bhl - \frac{1}{3}bh(l-L) = \frac{1}{6}bh3l - \frac{1}{6}bh2l + \frac{1}{6}bh2L = \frac{1}{6}bh(2L+l).$$

1. If the base of a wedge is 40 by 20 feet, the edge 35 feet, and the altitude 10 feet, what is the solidity?

*Ans.* 3833.33.

2. The base of a wedge being 18 feet by 9, the edge 20 feet, and the altitude 6 feet, what is the solidity?

*Ans.* 504.

### PROBLEM VIII.

To find the solidity of a rectangular prismoid.

**RULE.**—Add together the areas of the two bases and four times the area of a parallel section at equal distances from the bases: then multiply the sum by one-sixth of the altitude.

T

Let  $L$  and  $B$  be the length and breadth of the lower base,  $l$  and  $b$  the length and breadth of the upper base,  $M$  and  $m$  the length and breadth of the section equidistant from the bases, and  $h$  the altitude of the prismoid.

Through the diagonal edges  $L$  and  $l'$  let a plane be passed, and it will divide the prismoid into two wedges, having for bases, the bases of the prismoid, and for edges the lines  $L$  and  $l'=l$ .

The solidity of these wedges, and consequently of the prismoid, is

$$\frac{1}{6}Bh(2L+l) + \frac{1}{6}bh(2l+L) = \frac{1}{6}h(2BL + Bl + 2bl + bL).$$

But since  $M$  is equally distant from  $L$  and  $l$ , we have

$$2M = L + l, \quad \text{and} \quad 2m = B + b;$$

hence,  $4Mm = (L+l) \times (B+b) = BL + Bl + bL + bl$ .

Substituting  $4Mm$  for its value in the preceding equation, and we have for the solidity

$$\frac{1}{6}h(BL + bl + 4Mm).$$

**REMARK.**—This rule may be applied to any prismoid whatever. For, whatever be the form of the bases, there may be inscribed in each the same number of rectangles, and the number of these rectangles may be made so great that their sum in each base will differ from that base, by less than any assignable quantity. Now, if on these rectangles, rectangular prismoids be constructed, their sum will differ from the given prismoid by less than any assignable quantity. Hence the rule is general.

1. One of the bases of a rectangular prismoid is 25 feet by 20, the other 15 feet by 10, and the altitude 12 feet; required the solidity.

*Ans.* 3700.

2. What is the solidity of a stick of hewn timber, whose ends are 30 inches by 27, and 24 inches by 18, its length being 24 feet?

*Ans.* 102 feet.

#### OF THE MEASURES OF THE THREE ROUND BODIES.

##### PROBLEM IX.

To find the surface of a cylinder.

**RULE.**—Multiply the circumference of the base by the altitude and the product will be the convex surface (Book VIII. Prop. 1). To this add the areas of the two bases, when the entire surface is required.

1. What is the convex surface of a cylinder, the diameter of whose base is 20, and whose altitude is 50?

*Ans.* 3141.6.

2. Required the entire surface of a cylinder, whose altitude is 20 feet, and the diameter of its base 2 feet.

*Ans.* 131.9472.

PROBLEM X.

To find the convex surface of a cone.

**RULE.**—*Multiply the circumference of the base by half the side (Book VIII. Prop. III.): to which add the area of the base, when the entire surface is required.*

1. Required the convex surface of a cone, whose side is 50 feet, and the diameter of its base  $8\frac{1}{2}$  feet. *Ans.* 667.59.

2. Required the entire surface of a cone, whose side is 36 and the diameter of its base 18 feet. *Ans.* 1272.348.

PROBLEM XI.

To find the surface of the frustum of a cone.

**RULE.**—*Multiply the side of the frustum by half the sum of the circumferences of the two bases, for the convex surface (Book VIII. Prop. IV.): to which add the areas of the two bases, when the entire surface is required.*

1. To find the convex surface of the frustum of a cone, the side of the frustum being  $12\frac{1}{2}$  feet, and the circumferences of the bases 8.4 feet and 6 feet. *Ans.* 90.

2. To find the entire surface of the frustum of a cone, the side being 16 feet, and the radii of the bases 3 feet and 2 feet. *Ans.* 292.1688.

PROBLEM XII.

To find the solidity of a cylinder.

**RULE.**—*Multiply the area of the base by the altitude (Book VIII. Prop. II.).*

1. Required the solidity of a cylinder whose altitude is 12 feet, and the diameter of its base 15 feet. *Ans.* 2120.58.

2. Required the solidity of a cylinder whose altitude is 20 feet, and the circumference of whose base is 5 feet 6 inches. *Ans.* 48.144.

## PROBLEM XIII.

To find the solidity of a cone.

**RULE.**—*Multiply the area of the base by the altitude, and take one-third of the product (Book VIII. Prop. V.).*

1. Required the solidity of a cone whose altitude is 27 feet, and the diameter of the base 10 feet. *Ans.* 706.86.
2. Required the solidity of a cone whose altitude is  $10\frac{1}{2}$  feet, and the circumference of its base 9 feet. *Ans.* 22.56.

## PROBLEM XIV.

To find the solidity of the frustum of a cone.

**RULE.**—*Add together the areas of the two bases and a mean proportional between them, and then multiply the sum by one-third of the altitude (Book VIII. Prop. VI.).*

1. To find the solidity of the frustum of a cone, the altitude being 18, the diameter of the lower base 8, and that of the upper base 4. *Ans.* 527.7888.
2. What is the solidity of the frustum of a cone, the altitude being 25, the circumference of the lower base 20, and that of the upper base 10? *Ans.* 464.216.
3. If a cask, which is composed of two equal conic frustums joined together at their larger bases, have its bung diameter 28 inches, the head diameter 20 inches, and the length 40 inches how many gallons of wine will it contain, there being 231 cubic inches in a gallon? *Ans.* 79.0613.

## PROBLEM XV.

To find the surface of a sphere.

**RULE I.**—*Multiply the circumference of a great circle by the diameter (Book VIII. Prop. X.).*

**RULE II.**—*Multiply the square of the diameter, or four times the square of the radius, by 3.1416 (Book VIII. Prop. X. Cor.).*

1. Required the surface of a sphere whose diameter is 7. *Ans.* 153.9384.
2. Required the surface of a sphere whose diameter is 24 inches. *Ans.* 1809.5616 in.
3. Required the area of the surface of the earth, its diameter being 7921 miles. *Ans.* 197111024 sq. miles.
4. What is the surface of a sphere, the circumference of its great circle being 78.54? *Ans.* 1963.5.

PROBLEM XVI.

To find the surface of a spherical zone.

**RULE.**—*Multiply the altitude of the zone by the circumference of a great circle of the sphere, and the product will be the surface* (Book VIII. Prop. X. Sch. 1).

1. The diameter of a sphere being 42 inches, what is the convex surface of a zone whose altitude is 9 inches?

*Ans.* 1187.5248 sq. in.

2. If the diameter of a sphere is  $12\frac{1}{2}$  feet, what will be the surface of a zone whose altitude is 2 feet?

*Ans.* 78.54 sq. ft.

PROBLEM XVII.

To find the solidity of a sphere.

**RULE I.**—*Multiply the surface by one-third of the radius* (Book VIII. Prop. XIV.).

**RULE II.**—*Cube the diameter, and multiply the number thus found by  $\frac{1}{6}\pi$ : that is, by 0.5236* (Book VIII. Prop. XIV. Sch. 3).

1. What is the solidity of a sphere whose diameter is 12?

*Ans.* 904.7808.

2. What is the solidity of the earth, if the mean diameter be taken equal to 7918.7 miles?

*Ans.* 259992792083.

PROBLEM XVIII.

To find the solidity of a spherical segment.

**RULE.**—*Find the areas of the two bases, and multiply their sum by half the height of the segment; to this product add the solidity of a sphere whose diameter is equal to the height of the segment* (Book VIII. Prop. XVII.).

**REMARK.**—When the segment has but one base, the other is to be considered equal to 0 (Book VIII. Def. 14).

1. What is the solidity of a spherical segment, the diameter of the sphere being 40, and the distances from the centre to the bases, 16 and 10.

*Ans.* 4297.7088.

2. What is the solidity of a spherical segment with one base the diameter of the sphere being 8, and the altitude of the segment 2 feet?

*Ans.* 41.888.

3. What is the solidity of a spherical segment with one base, the diameter of the sphere being 20, and the altitude of the segment 9 feet?

*Ans.* 1781.2872.

#### PROBLEM XIX.

To find the surface of a spherical triangle.

**RULE.**—1. *Compute the surface of the sphere on which the triangle is formed, and divide it by 8; the quotient will be the surface of the tri-rectangular triangle.*

2. *Add the three angles together; from their sum subtract  $180^\circ$ , and divide the remainder by  $90^\circ$ : then multiply the tri-rectangular triangle by this quotient, and the product will be the surface of the triangle (Book IX. Prop. XX.).*

1. Required the surface of a triangle described on a sphere whose diameter is 30 feet, the angles being  $140^\circ$ ,  $92^\circ$ , and  $68^\circ$ .

*Ans.* 471.24 sq. ft.

2. Required the surface of a triangle described on a sphere of 20 feet diameter, the angles being  $120^\circ$  each.

*Ans.* 314.16 sq. ft.

#### PROBLEM XX.

To find the surface of a spherical polygon.

**RULE.**—1. *Find the tri-rectangular triangle, as before.*

2. *From the sum of all the angles take the product of two right angles by the number of sides less two. Divide the remainder by  $90^\circ$ , and multiply the tri-rectangular triangle by the quotient: the product will be the surface of the polygon (Book IX. Prop. XXI.).*

1. What is the surface of a polygon of seven sides, described on a sphere whose diameter is 17 feet, the sum of the angles being  $1080^\circ$ ?

*Ans.* 226.98.

2. What is the surface of a regular polygon of eight sides, described on a sphere whose diameter is 30, each angle of the polygon being  $140^\circ$ ?

*Ans.* 157.08

#### OF THE REGULAR POLYEDRONS.

In determining the solidities of the regular polyedrons, it becomes necessary to know, for each of them, the angle contained between any two of the adjacent faces. The determination of this angle involves the following property of a regular polygon, viz.—

*Half the diagonal which joins the extremities of two adjacent sides of a regular polygon, is equal to the side of the polygon multiplied by the cosine of the angle which is obtained by dividing  $360^\circ$  by twice the number of sides: the radius being equal to unity.*

Let ABCDE be any regular polygon. Draw the diagonal AC, and from the centre F draw FG, perpendicular to AB. Draw also AF, FB; the latter will be perpendicular to the diagonal AC, and will bisect it at H (Book III. Prop. VI. Sch.).

Let the number of sides of the polygon be designated by  $n$ : then,

$$AFB = \frac{360^\circ}{n}, \quad \text{and} \quad AFG = CAB = \frac{360^\circ}{2n}.$$

But in the right-angled triangle ABH, we have

$$AH = AB \cos A = AB \cos \frac{360^\circ}{2n} \quad (\text{Trig. Th. I. Cor.})$$

**REMARK 1.**—When the polygon in question is the equilateral triangle, the diagonal becomes a side, and consequently half the diagonal becomes half a side of the triangle.

**REMARK 2.**—The perpendicular  $BH = AB \sin \frac{360^\circ}{2n}$  (Trig. Th. I. Cor.).

To determine the angle included between the two adjacent faces of either of the regular polyedrons, let us suppose a plane to be passed perpendicular to the axis of a solid angle, and through the vertices of the solid angles which lie adjacent. This plane will intersect the convex surface of the polyedron in a regular polygon; the number of sides of this polygon will be equal to the number of planes which meet at the vertex of either of the solid angles, and each side will be a diagonal of one of the equal faces of the polyedron.

Let D be the vertex of a solid angle, CD the intersection of two adjacent faces, and ABC the section made in the convex surface of the polyedron by a plane perpendicular to the axis through D.

Through AB let a plane be drawn perpendicular to CD, produced if necessary, and suppose AE, BE, to be the lines in

which this plane intersects the adjacent faces. Then will AEB be the angle included between the adjacent faces, and FEB will be half that angle, which we will represent by  $\frac{1}{2}A$ .

Then, if we represent by  $n$  the number of faces which meet at the vertex of the solid angle, and by  $m$  the number of sides of each face. we shall have, from what has already been shown,

$$BF = BC \cos \frac{360^\circ}{2n}, \quad \text{and} \quad EB = BC \sin \frac{360^\circ}{2m}.$$

But  $\frac{BF}{EB} = \sin FEB = \sin \frac{1}{2}A$ , to the radius of unity ;

hence, 
$$\sin \frac{1}{2}A = \frac{\cos \frac{360^\circ}{2n}}{\sin \frac{360^\circ}{2m}}.$$

This formula gives, for the plane angle formed by every two adjacent faces of the

|                       |              |
|-----------------------|--------------|
| Tetraedron . . . . .  | 70° 31' 42"  |
| Hexaedron . . . . .   | 90°          |
| Octaedron . . . . .   | 109° 28' 18" |
| Dodecaedron . . . . . | 116° 33' 54" |
| Icosaedron . . . . .  | 138° 11' 23" |

Having thus found the angle included between the adjacent faces, we can easily calculate the perpendicular let fall from the centre of the polyedron on one of its faces, when the faces themselves are known.

The following table shows the solidities and surfaces of the regular polyedrons, when the edges are equal to 1.

A TABLE OF THE REGULAR POLYEDRONS WHOSE EDGES ARE 1.

| Names.                | No. of Faces. | Surface.             | Solidity. |
|-----------------------|---------------|----------------------|-----------|
| Tetraedron . . . . .  | 4 . . . . .   | 1.7320508 . . . . .  | 0.1178513 |
| Hexaedron . . . . .   | 6 . . . . .   | 6.0000000 . . . . .  | 1.0000000 |
| Octaedron . . . . .   | 8 . . . . .   | 3.4641016 . . . . .  | 0.4714045 |
| Dodecaedron . . . . . | 12 . . . . .  | 20.6457288 . . . . . | 7.6631189 |
| Icosaedron . . . . .  | 20 . . . . .  | 8.6602540 . . . . .  | 2.1816950 |

## PROBLEM XXI.

To find the solidity of a regular polyedron.

**RULE I.**—*Multiply the surface by one-third of the perpendicular let fall from the centre on one of the faces, and the product will be the solidity.*

**RULE II.**—*Multiply the cube of one of the edges by the solidity of a similar polyedron, whose edge is 1.*

The first rule results from the division of the polyedron into as many equal pyramids as it has faces. The second is proved by considering that two regular polyedrons having the same number of faces may be divided into an equal number of similar pyramids, and that the sum of the pyramids which make up one of the polyedrons will be to the sum of the pyramids which make up the other polyedron, as a pyramid of the first sum to a pyramid of the second (Book II. Prop. X.); that is, as the cubes of their homologous edges (Book VII. Prop. XX.); that is, as the cubes of the edges of the polyedron.

1. What is the solidity of a tetraedron whose edge is 15?

*Ans.* 397.75.

2. What is the solidity of a hexaedron whose edge is 12?

*Ans.* 1728.

3. What is the solidity of a octaedron whose edge is 20?

*Ans.* 3771.236.

4. What is the solidity of a dodecaedron whose edge is 25?

*Ans.* 119736.2328.

5. What is the solidity of an icosaedron whose side is 20?

*Ans.* 17453.56.

**A TABLE**  
**OF**  
**LOGARITHMIC**  
**SINES AND TANGENTS**  
**FOR EVERY**  
**DEGREE AND MINUTE**  
**OF THE QUADRANT.**

---

**N. B** The minutes in the left-hand column of each page, increasing downwards, belong to the degrees at the top; and those increasing upwards, in the right-hand column, belong to the degrees below.

| M. | Sine     | D.     | Cosine    | D. | Tang.    | D.     | Cotang.   |    |
